Conditional Betas, Higher Comoments and the Cross-Section of Expected Stock Returns

by

Lei Xu

Submitted by Lei Xu, to the University of Exeter as a thesis for the degree of Doctor of Philosophy in Finance, June 2010.

This thesis is available for Library use on the understanding that it is copyright material and that no quotation from this thesis may be published without proper acknowledgement.

I certify that all material in this thesis which is not my own work has been identified and that no material has previously been submitted and approved for the award of a degree by this or any other University.
To my parents
Acknowledgements

My deepest gratitude goes first and foremost to Professor Richard Harris, my supervisor, for his constant encouragement and guidance. He has walked me through all the stages of the writing of this thesis. Without his consistent and illuminating instruction, this thesis could not have reached its present form.

I would also like to acknowledge Dr. Cherif Guermet and Dr. Zhenxu Tong for very helpful instructions and Dr. Jian Shen for her help with data.

This thesis is dedicated to my parents. I would like to take this opportunity to say thank you to my beloved parents for their loving consideration and great confidence in me through all these years. Without your support and encouragement, I could not afford to come to the UK and finish my PhD and master’s degree in Exeter.

Special thanks go to Mrs. Kath Dugdale and Mr. Bernard Dugdale for providing me with accommodation and correcting the grammar of this thesis. I really enjoyed my time living with you.

I gratefully acknowledge the financial support from the Business School of the University of Exeter in the form of a graduate teaching assistantship. It gave me sufficient funding and valuable teaching experience.
Abstract

This thesis examines the performance of different models of conditional betas and higher comoments in the context of the cross-section of expected stock returns, both in-sample and out-of-sample.

I first examine the performance of different conditional market beta models by using monthly returns of the Fama-French 25 portfolios formed by the quintiles of size and book-to-market ratio in Chapter 3. This is a cross-sectional test of the conditional CAPM. The models examined include simple OLS regressions, the macroeconomic variables model, the state-space model, the multivariate GARCH model and the realized beta model. The results show that the state-space model performs best in-sample with significant betas and insignificant intercepts. For the out-of-sample performance, however, none of the models examined can explain returns of the 25 portfolios.

Next, I examine the recently proposed realized beta model, which is based on the realized volatility literature, by using individual stocks listed in the US market in Chapter 4. I extend the realized market beta model to betas of multi-factor asset pricing models. Models tested are the CAPM, the Fama-French three-factor model and a four-factor model including the three Fama-French factors and a momentum factor. Realized betas of different models are used in the cross-section regressions along with firm-level variables such as size, book-to-market ratio and past returns. The in-sample results show that market beta is significant and additional betas of multi-factor models can reduce although not eliminate the effects of firm-level variables. The out-of-sample results show that no betas are significant. The results are robust across different markets such as NYSE, AMEX and NASDAQ.

In Chapter 5, I test if realized coskewness and cokurtosis can help explain the cross-section of stock returns. I add coskewness and cokurtosis to the factor pricing models tested in Chapter 4. The results show that the coefficients of coskewness and cokurtosis have the correct sign as predicted by the higher-moment CAPM theory but only cokurtosis is significant. Cokurtosis is significant not only in-sample but also out-of-sample, suggesting
Cokurtosis is an important risk. However, the effects of firm-level variables remain significant after higher moments are included, indicating a rejection of higher-moment asset pricing models. The results are also robust across different markets such as NYSE, AMEX and NASDAQ.

The overall results of this thesis indicate a rejection of the conditional asset pricing models. Models of systematic risks, i.e. betas and higher comoments, cannot explain the cross-section of expected stock returns.
Table of Contents

List of Tables and Figures................................................................. 13
Abbreviations ...................................................................................... 15

Chapter 1  Introduction..................................................................... 17
1.1 Background.................................................................................. 17
1.2 Motivation.................................................................................... 20
1.3 Contributions................................................................................ 21
1.4 Empirical results.......................................................................... 23
1.5 Conclusion..................................................................................... 24
1.6 Organization of this thesis............................................................ 25

Chapter 2  Literature Review............................................................. 27
2.1 Mean-variance analysis and the CAPM ........................................ 28
   2.1.1 Mean-variance analysis.............................................................. 28
   2.1.2 The Sharpe-Lintner CAPM....................................................... 29
   2.1.3 The conditional CAPM of Hansen and Richard ....................... 31
2.2 Empirical tests of the CAPM........................................................ 33
   2.2.1 Early empirical tests of the CAPM.......................................... 34
   2.2.2 Recent tests: the CAPM and the cross-section of expected returns .... 36
2.3 Explanations: what causes the failure of the CAPM?.................... 38
   2.3.1 The conditional CAPM........................................................... 39
   2.3.2 Multi-factor models.............................................................. 44
   2.3.3 The higher-moment CAPM.................................................... 46
   2.3.4 Other explanations............................................................... 47
2.4 Conclusion.................................................................................... 49

Chapter 3  Conditional Market Beta and the Cross-Section of Stock Returns .... 51
3.1. Introduction................................................................................ 51
3.2. Empirical framework............................................................... 55
   3.2.1 The unconditional CAPM and constant beta ...................... 55
3.2.2 The conditional CAPM and models of time-varying beta

3.2.2.1 The short-window regression

3.2.2.2 The macroeconomic variables model

3.2.2.3 The state-space model

3.2.2.4 The DCC-GARCH model

3.2.2.5 The realized beta model

3.2.3 The Fama-MacBeth approach

3.3. Data

3.3.1 Market and individual portfolio returns

3.3.2 Macroeconomic variables

3.3.3 Summary statistics

3.4 Empirical results

3.4.1 Estimation of conditional market beta models

3.4.1.1 The macroeconomic variables model

3.4.1.2 The state-space model

3.4.1.3 The DCC-GARCH(1,1) model

3.4.1.4 The realized beta model

3.4.2 A comparison of the different models

3.4.3 Cross-sectional regression results

3.4.3.1 In-sample estimated market beta

3.4.3.2 Out-of-sample forecasted market beta

3.5 Conclusion
