Acknowledgements
I would like to extend my sincere gratitude to supervisor Dr. Rod Wilson for all his encouragement, advice and for offering the benefits of his knowledge and experience over many enjoyable discussions throughout the course of this project. Likewise, I am also very grateful to friend and colleague Dr. Chris Cooper, with whom it has been a pleasure to work these past few years. In addition, I would like to thank Jan Shears and Margaret Grapes for their excellent technical assistance. Thank you also to Dr Martin Grosell at the University of Miami for the opportunity to visit his laboratory, as well as Josi Taylor, Janet Genz and the rest of his research group for their wonderful hospitality. I would also like to thank the many members (past and present) of the Ecotoxicology and Ecophysiology research group here at the School of Biosciences. Finally, I wish to express my deep gratitude to my family for their encouragement and support throughout.

This work was funded by a studentship from the Biotechnology and Biological Sciences Research Council (BBSRC).

Abstract
In seawater, drinking is a fundamental part of the osmoregulatory strategy for teleost fish, and presents a unique challenge. The intestine has an established role in osmoregulation, and its ability to effectively absorb fluid from imbibed seawater is crucial to compensating for water losses to the surrounding hyperosmotic environment. Alongside solute-linked water transport (driven by NaCl cotransport), intestinal bicarbonate (HCO$_3^-$) secretion also benefits fluid absorption directly (via apical Cl$^-$/HCO$_3^-$ exchange), and indirectly through the formation of calcium carbonate (CaCO$_3$) thus removing the osmotic influence of Ca$^{2+}$ within the gut fluid. For the European flounder (*Platichthys flesus*), elevated luminal Ca$^{2+}$ has proven to be a specific, potent stimulator of HCO$_3^-$ secretion both *in vitro* and *in vivo* where these actions are presumably modulated by an extracellular Ca$^{2+}$-sensing receptor (CaR). The focus of this work was to learn more about how intestinal HCO$_3^-$ secretion is regulated, the role of Ca$^{2+}$, and more specifically the CaR. To achieve this, *in vitro* ‘gut sac’ experiments investigated how luminal Ca$^{2+}$ influenced HCO$_3^-$ secretion, and associated ion and fluid transport. Contrary to expectation, increasing Ca$^{2+}$ from 5 to 20 mM did not stimulate HCO$_3^-$ secretion. In an attempt to elucidate the role of CaCO$_3$ precipitation in fluid absorption, and further explore the physiological implications of HCO$_3^-$ secretion, the intestine was perfused *in vivo* with salines containing varying concentrations of Ca$^{2+}$ (10, 40 and 90 mM). The production and secretion of HCO$_3^-$, in addition to CaCO$_3$ formation increased accordingly with Ca$^{2+}$, and was associated with a dramatic 25% rise in the fraction of fluid absorbed by the gut. Additional *in vitro* experiments, utilising the Ussing chamber, helped establish some of the characteristics of intestinal HCO$_3^-$ secretion by the euryhaline killifish (*Fundulus heteroclitus*), but was unresponsive to elevated mucosal Ca$^{2+}$. Further attempts to potentiate the activity of the CaR, and application of the receptor agonists gadolinium (Gd$^{3+}$) and neomycin, failed to produce responses consistent with the effect of Ca$^{2+}$ observed previously, either *in vitro* or *in vivo*. With no evidence supporting a direct role for an extracellular, intestinal CaR in HCO$_3^-$ secretion it was argued that secretion would be principally regulated by two factors, the ability of the epithelia to generate high levels of intracellular HCO$_3^-$ and the rate of CaCO$_3$ formation.

Chapter 1 – Introduction

1. The challenge of life in the sea
   1.1 Osmoconformity
   1.2 Osmoregulation
2. The osmoregulatory strategy of marine teleost fish
   2.1 Drinking
   2.2 Processing imbibed seawater
     2.2.1 The gastrointestinal tract
     2.2.2 Oesophagus
     2.2.3 Intestine
     2.2.4 Gills
     2.2.5 Kidney and urinary bladder
3. The role of the intestine in osmoregulation
   3.1 Anatomical structure
   3.2 Ion transport
   3.3 Fluid transport
     3.3.1 Aquaporins
     3.3.2 Is there active fluid transport?
     3.3.3 Calcium carbonate precipitation
4. Regulation of intestinal HCO₃⁻ secretion
   4.1 Osmoregulation and intestinal HCO₃⁻ secretion
   4.2 The calcium-sensing receptor (CaR)
     4.2.1 Structure and diversity
     4.2.2 Agonists and modulators
     4.2.3 Tissue distribution and functions
     4.2.4 Roles in health and disease
   4.3 The CaR in teleosts
     4.3.1 Distribution and proposed functions
     4.3.2 A role for the CaR in marine teleost osmoregulation
5. Project overview

Chapter 2 – Measuring fluid transport in vitro: Gravimetric method versus non-absorbable marker

1. Summary
2. Introduction
   2.1 Development of the gut sac as an in vitro technique
   2.2 Measuring fluid transport by gut sacs
   2.3 Non-absorbable volume markers
   2.4 Using PEG as a marker
   2.5 Aims and objectives
3. Materials and Methods
   3.1 Experimental animals
Chapter 3 – Evaluating the paired gut sac technique for measurement of ion and fluid transport in vitro

1. Summary

2. Introduction
   2.1 Assessing the viability of the intestine in vitro
   2.2 The energetic requirements of the intestine
   2.3 The functional capacity of the intestine in vitro
   2.4 Glucose and glutamine as metabolic fuels
   2.5 Aims and objectives

3. Materials and Methods
   3.1 Experimental animals
   3.2 Saline design and composition
   3.3 Concentrations of glucose and glutamine
   3.4 Pre-incubation period
   3.5 Functional viability of the gut sac preparation
   3.6 Hydrostatic pressure effects

**Figure 7.2:** The mean net fluxes of \( \text{Na}^+ \), \( \text{Cl}^- \) and \( \text{HCO}_3^- \), alongside net fluid transport by gut sacs from the flounder intestine under control conditions, and in response to a 15 mM increase in mucosal \( \text{Ca}^{2+} \) concentration using the ‘reduced ionic strength’ mucosal saline.

**Figure 7.3:** The mean net fluxes of \( \text{Na}^+ \), \( \text{Cl}^- \) and \( \text{HCO}_3^- \), alongside net fluid transport by gut sacs from the flounder intestine under control conditions, and in response to a 15 mM increase in mucosal \( \text{Ca}^{2+} \) concentration using the ‘reduced osmolality’ mucosal saline.

**Figure 7.4:** The mean net fluxes of \( \text{Na}^+ \), \( \text{Cl}^- \) and \( \text{HCO}_3^- \), alongside net fluid transport by gut sacs from the flounder intestine under control conditions, and in response to \( \text{Gd}^{3+} \).

**Figure 7.5:** The mean net fluxes of \( \text{Na}^+ \), \( \text{Cl}^- \) and \( \text{HCO}_3^- \), alongside net fluid transport by gut sacs from the flounder intestine under control conditions, and in response to neomycin.

**Figure 7.6:** The mean net production and excretion of \( \text{HCO}_3^- \) equivalents by the intestine of the flounder perfused with salines containing the CaR agonists \( \text{Gd}^{3+} \) or neomycin.

**Figure 7.7:** The mean proportion of fluid absorbed by the flounder intestine following perfusion with salines containing the CaR agonists \( \text{Gd}^{3+} \) or neomycin.

**Figure 7.8:** (A) Mucus globules exiting from the goblet cell, demonstrating how \( \text{Ca}^{2+} \) becomes concentrated in the mucus. (B) Needle-like \( \text{Ca}^{2+} \)-rich crystals are clearly visible within the overlying mucus layer. (C) A simple schematic diagram
illustrating the potential role for CaCO$_3$ crystallisation in HCO$_3$\(^-\) secretion.

**Figure 7.9**: The mean net Na\(^+\) and Cl\(^-\) fluxes by the intestine of the flounder perfused with salines containing the CaR agonists Gd\(^{3+}\) and neomycin.

**Figure 7.10**: The net fluxes of Cl\(^-\) and HCO$_3$\(^-\) in relation to net fluid transport using the overall mean values pooled from anterior, mid and posterior gut sacs.

**Figure 7.11**: The relationships between net sodium flux, net fluid transport rate, and the concentration of Na\(^+\) in the mucosal saline with gut sacs from the European flounder

**Figure 8.1**: The concentration of HCO$_3$\(^-\) in the anterior, mid, posterior and rectal fluids sampled from the intestine of the Gulf toadfish (*Opsanus beta*) acclimated to a range of salinities from 2.5 to 70 ppt.

---

**List of Tables**

---
**Table 5.1:** The inorganic salts used in the composition of the *in vivo* perfusion salines employed by the present study.

**Table 5.2:** The mean values for measurements of pH, TCO₂ and calculated HCO₃⁻ equivalents measured in rectal fluid samples from the flounder following perfusion of the intestine.

**Table 5.3:** A summary of the various acid-base and osmoregulatory parameters measured on whole blood (pH) and plasma (Osmolality, TCO₂, Na⁺, Cl⁻, K⁺, Ca²⁺, and Mg²⁺) as part of the daily blood sampling routine during perfusion of the flounder intestine.

**Table 5.4:** The ionic composition of the rectal fluid following intestinal perfusion.

**Table 6.1:** The composition of the mucosal and serosal salines.

**Table 6.2:** A comparison of the ionic composition of the ‘regular’ mucosal saline used in the present study with the mucosal saline used by Wilson *et al.* (2002).

**Table 7.1:** The inorganic salts and additional solutes used in the composition of the mucosal and serosal salines.

**Table 7.2:** The inorganic salts used in the composition of the *in vivo* perfusion salines.

**Table 7.3:** The mean values of pH, TCO₂ and calculated HCO₃⁻ equivalents measured in rectal fluid samples from the flounder following perfusion of the intestine with salines containing the CaR agonists, Gd³⁺ and neomycin.

**Table 7.4:** The electrochemical potentials of Cl⁻ and HCO₃⁻ across the intestinal epithelia of the European flounder at the beginning and the end of *in vitro* gut sac experiments.

**Table 7.5:** A comparison of the electrochemical potentials for Na⁺, K⁺ and Cl⁻ as well as apical NaCl co-transport, for the ‘regular’ mucosal saline and ‘reduced ionic strength’ mucosal saline used with gut sacs from the intestine of the European flounder.

**Table 8.1:** The reduction in osmotic pressure of fluid absorbed by the teleost intestine *in vitro*, following the buffering of absorbed H⁺ by the extracellular fluid.
List of Plates

**Plate 5.1**: A flounder under anaesthesia on the wet table the gills being irrigated *via* the mouth and implantation of the blood catheter. 

**Plate 5.2**: Insertion of the stomach drain catheter and intestinal perfusion catheter. 

**Plate 5.3**: Fitting the rectal catheter. 

**Plate 6.1**: The Ussing chamber set up with pH stat.
