I certify that all material in this thesis which is not my own work has been identified and that no material has previously been submitted and approved for the award of a degree by this or any other University.

Yvonne Roger
Abstract

Cytoplasmic dynein is a microtubule-dependent motor protein which participates in numerous cellular processes. The motor complex consists of two heavy chains, intermediate, light intermediate and 3 families of light chains. Dynein is able to bind to these accessory chains as well as to regulatory proteins which enables the motor protein to fulfil such a variety of cellular processes. The associated light chains participate in long-distance organelle and vesicle transport in interphase and in chromosome segregation during mitosis. However, how these light chains control the activity of the motor protein is still unknown.

In this study, I combine molecular genetics and live cell imaging to elucidate the role of the associated dynein light intermediate and light chains in dynein behaviour and early endosome (EE) motility in hyphal interphase cells as well as the anchorage of dynein to the microtubule (MT) plus-end in interphase and mitotic cells. I show that the dynein light intermediate chain (DLIC) as well as the light chain 2 (DLC2, Roadblock) are involved in dynein processivity and EE movement in interphase. The downregulation of either protein results in short hyphal growth which could be caused by a decreased runlength of EE and dynein. In addition, both proteins participate in dynein anchorage to the microtubule plus-end in interphase and mitosis as well as in spindle elongation during mitosis. Each protein causes a decrease of the motor protein dynein at MT plus-ends. Surprisingly, I found only minor or no defects in LC8 or Tctex mutants in the observed functions of dynein. LC8 seems to affect the dynein but not the EE runlength. In this case, dynein is still able to move into the bipolar MT array from where kinesin3 is able to take over EEs and move them towards the cell center. In contrast, Tctex has no effect on dynein or EE runlength or any other observed dynein function in hyphal cells. However, it causes a reduction in spindle
elongation. Taken together, DLIC and DLC2 are important for dynein behaviour in long distance transport as well as in spindle positioning and elongation during mitosis.

Furthermore, I studied the involvement of the dynein regulators Lis1 and NudE as well as the plus-end binding protein Clip1 (Clip-170 homologue) in the anchorage of dynein to the astral microtubule plus-ends during mitosis. The disruption of the anchorage complex at the astral MT plus-end causes a decrease in dynein number at this site and therefore slower spindle elongation in Anaphase B. Taken together, all three proteins are involved in anchorage of dynein to the astral microtubule tip and the subsequent spindle elongation. Furthermore, these findings also show that *Ustilago maydis* evolved two different mechanisms to anchor the motor protein to MT plus-ends in hyphal and mitotic cells. The plus-end binding protein Peb1 (EB1 homologue) and the dynein regulator dynactin mediate the dynein anchorage in hyphal cells whereas in mitotic cells the plus-ends binding protein Clip1 and the dynein regulators Lis1 and NudE anchor dynein to astral MT plus-ends.

1.5. The model organism *Ustilago maydis* 42

1.6. Objectives 44

2. Results 46

2.1. The dynein motor complex in *Ustilago maydis* –

DLIC and LC “Roadblock” are important for its function 46

Abstract 48

Introduction 49

Results 51

The dynein intermediate light chain and the light chain "roadblock" are essential for hyphal cell morphogenesis 52

Retrograde motility of early endosomes depends on DLIC and DLC2 54

Dynein motility is impaired in LC8↓, DLIC↓ and DLC2↓ mutants 55

The DLIC and the light chain "roadblock" regulate the amount of dynein at interphase microtubule plus-ends 56

The DLIC, DLC2 and LC8 are involved in mitotic spindle positioning and elongation 57

Absence of DLIC and DLC2 reduces the number of dynein motors at plus-ends of astral MTs 58

Discussion 60

The model fungus *U. maydis* contains all pivotal dynein components 61

DLIC and DLC2 are essential for retrograde endosome transport 62

DLIC and DLC2 are essential for anaphase spindle elongation 63

A mutant in a distant Tctex homologue shows defects in spindle elongation 64

The light chain LC8 affects dynein processivity, but not the run-length of endosomes 65

Conclusion 66
Material and Methods

2.2. The microtubule plus-end capture of dynein

Abstract

Introduction

Results

Dynein is required for spindle positioning and anaphase B
spindle elongation

Dynein anchorage at plus-ends of aMTs does not depend on a
dynactin-EB1 interaction

Clip1 supports prophase spindle positioning and anaphase B by
Increasing dynein numbers at aMT tips

Lis1 supports spindle elongation by anchoring dynein and doubling
the off-loading rate

Dynein anchorage involves NudE

Discussion
3. **General conclusion**

3.1. Dynein associates with accessory chains to increase its processivity in long distance transport in interphase cells

3.2. The accessory dynein light chains increase the motor efficiency in mitosis

3.3. Different dynein anchorage mechanisms in mitotic and interphase cells

3.4. Summary and Outlook
