The dependence of macroscopic radiation pressure on the velocity of the object being pushed is commonly attributed to the Doppler effect. This need not be the case, and here we highlight velocity dependent radiation pressure terms that have their origins in the mixing of s and p polarizations brought about by the Lorentz transformation between the lab and the material rest frame, rather than in the corresponding transformation of frequency and wavevector. The theory we develop is relevant to the nano-optomechanics of moving bodies. © 2012 Optical Society of America

1. Introduction

Radiation pressure arises from the momentum of light and depends upon the velocity of the body being pushed [1, 2]. Take light incident onto the surface of a perfectly reflecting mirror that moves along the surface normal: in the mirror rest frame, the momentum and rate of arrival of the incident photons will appear either increased or decreased relative to the laboratory, depending on whether the mirror moves towards, or away from the light source. This is a consequence of the Doppler effect, and implies that the velocity dependent part of the radiation pressure acts to slow the mirror down. When attached to an oscillatory degree of freedom this effect appears as a friction-like term in the equation of motion and is therefore termed *radiation damping*. For highly dispersive mirrors (e.g. a Bragg mirror),

the reflection coefficient of the moving medium is also strongly dependent upon the Doppler shifted frequency, and this can turn damping into heating [3, 4].

The relative motion of a dielectric medium in general has a peculiar effect on the polarization of light as well as its propagation. The moving medium behaves as a magnetoelectric [5, 6], which implies a change in the polarization composition (s & p) upon interacting with the medium. In spite of the fact that many features of reflection from, and transmission through moving dielectrics have been considered before [7–9], here we raise the question whether there exist optical forces, at least from a classical standpoint, arising from polarization mixing effects in a moving medium¹. We find that there are situations where polarization mixing effects occur at the same order of V/c as the Doppler effect, and cannot be neglected. Our theoretical framework, based on generalized scattering matrix methods, is readily amenable to single out these non-Doppler contributions to the radiation pressure experienced by a moving dielectric. We further examine a clear-cut configuration where the effect of radiation pressure is solely due to polarization mixing.

2. Transformation of field amplitudes between reference frames

The laboratory frame electromagnetic field, exerting pressure on a moving dielectric slab (see figure 1) can be written as,

$$\mathbf{E}(\mathbf{x}, t) = \sum_{\pm} \sum_{q=1,2} \hat{\mathbf{e}}_q^{(\pm)} \alpha_q^{(\pm)} e^{i(\mathbf{k}^{(\pm)} \cdot \mathbf{x} - \omega t)}. \quad (1)$$

$$\mathbf{B}(\mathbf{x}, t) = \frac{1}{c} \sum_{\pm} \sum_{q=1,2} (-1)^{\bar{q}} \hat{\mathbf{e}}_{\bar{q}}^{(\pm)} \alpha_q^{(\pm)} e^{i(\mathbf{k}^{(\pm)} \cdot \mathbf{x} - \omega t)} \quad (2)$$

where the surface has a normal parallel to $\hat{\mathbf{x}}$, $\mathbf{k}_{\parallel} = k_y \hat{\mathbf{y}} + k_z \hat{\mathbf{z}}$ and $\mathbf{k}^{(\pm)} = \pm |k_x| \hat{\mathbf{x}} + \mathbf{k}_{\parallel}$, with all the wavevector components real, and choosing polarization unit vectors $\hat{\mathbf{e}}_1^{(\pm)} = \hat{\mathbf{e}}_1 = \hat{\mathbf{x}} \times \hat{\mathbf{k}}_{\parallel}$, $\hat{\mathbf{e}}_2^{(\pm)} = \hat{\mathbf{k}}^{(\pm)} \times \hat{\mathbf{e}}_1$, that are equivalent to s ($q = 1$) and p ($q = 2$) polarization. The barred index is defined as $\bar{q} = q + 1 \pmod{2}$.

A Lorentz transformation of (1–2) shows that for *transverse* motion $\mathbf{V} = V_x \hat{\mathbf{x}}$ the rest and laboratory frame field amplitudes are related by a constant of proportionality. For instance, inserting (1) and its primed counterpart into $E'_x = E_x$, we have

$$\sum_{\pm} \alpha_2'^{(\pm)} \left(\frac{ck_{\parallel}}{\omega'^{(\pm)}} \right) e^{i(\mathbf{k}^{(\pm)} \cdot \mathbf{x} - \omega t)} = \sum_{\pm} \alpha_2^{(\pm)} \left(\frac{ck_{\parallel}}{\omega} \right) e^{i(\mathbf{k}^{(\pm)} \cdot \mathbf{x} - \omega t)} \quad (3)$$

¹There has been some debate surrounding the role of the mixing of polarizations in the lateral Casimir force between moving plates (Casimir friction). On one side it has been argued that there should be a frictional force between the plates [10], but this calculation ignores the mixing of polarizations. Another calculation, which takes these into account [11] has claimed a zero value for the frictional force.

where $\omega'^{(\pm)} = \gamma(\omega \mp V_x|k_x|)$ and $\gamma = (1 - \mathbf{V}^2/c^2)^{-1/2}$. The equality (3) is satisfied if $\alpha_2'^{(\pm)} = (\omega'^{(\pm)}/\omega)\alpha_2^{(\pm)}$, and examining the remaining components of the field we find in general

$$\alpha_i'^{(\pm)} = (\omega'^{(\pm)}/\omega)\alpha_i^{(\pm)} \quad (4)$$

It is therefore evident that polarizations are not mixed by media moving in a direction parallel to their surface normal: the ratio of s and p polarizations will be maintained in transmission through and reflection from a transversely moving medium. This is the case for the radiation damping effect mentioned in the introduction, the physics of which is captured within (4).

Meanwhile for *lateral* motion ($\mathbf{V} = V_y\hat{\mathbf{y}}$), we find that polarizations are mixed by the motion. Consider again the Lorentz transformation of the x component of the electric field, (1) from the laboratory into the medium rest frame $E'_x = \gamma(E_x + V_yB_z)$. Using (1–2) this transformation gives the condition

$$\sum_{\pm} \alpha_2'^{(\pm)} \hat{e}_{2x}^{(\pm)} e^{i(\mathbf{k}^{(\pm)} \cdot \mathbf{x} - \omega t)} = \sum_{\pm} \gamma [\alpha_2^{(\pm)} (\hat{e}_{2x}^{(\pm)} - V_y \hat{e}_{1z}^{(\pm)}/c) + (V_y/c) \alpha_1^{(\pm)} \hat{e}_{2z}^{(\pm)}] e^{i(\mathbf{k}^{(\pm)} \cdot \mathbf{x} - \omega t)} \quad (5)$$

where $\omega' = \gamma(\omega - V_y k_y)$. After the components of the unit vectors have been written in terms of $\omega, \omega', \mathbf{k}$ and \mathbf{k}' , (5) is equivalent to

$$\alpha_2'^{(\pm)} = \left(\frac{\omega'}{\omega} \right) \frac{\alpha_2^{(\pm)} \mp (V_y \eta/c) \alpha_1^{(\pm)}}{\sqrt{1 + V_y^2 \eta^2/c^2}} \quad (6)$$

with $\eta = |k_x|k_z/(k_{\parallel}^2 - V_y \omega k_y/c^2)$. Examining the remaining components of the electric field reveals that the same relationship also holds for the s -polarization, but with $\eta \rightarrow -\eta$. This transformation of the field amplitudes can be summarized concisely in matrix form if we introduce the four component vector², $\boldsymbol{\alpha}^T = (\alpha_1^{(+)}, \alpha_1^{(-)}, \alpha_2^{(+)}, \alpha_2^{(-)})$. Then the transformation can be written as

$$\boldsymbol{\alpha}' = \left(\frac{\omega'}{\omega} \right) \mathbf{M} \cdot \boldsymbol{\alpha} \quad (7)$$

with

$$\mathbf{M} = \frac{1}{\sqrt{1 + \frac{\eta^2 V_y^2}{c^2}}} \begin{pmatrix} \mathbb{1}_2 & \frac{V_y \eta}{c} \boldsymbol{\sigma}_z \\ -\frac{V_y \eta}{c} \boldsymbol{\sigma}_z & \mathbb{1}_2 \end{pmatrix}, \quad (8)$$

and where $\boldsymbol{\sigma}_z$ is the usual Pauli matrix. We can now see that the situation is different for dielectric media in lateral motion where the electromagnetic field is modified both by the change of frequency and wave-vector, and by the composition of the polarization (7–8). The unitary 4×4 matrix \mathbf{M} describes how the two polarizations are coupled by the motion of the medium, and this specifically hinges on the off diagonal 2×2 matrices $\pm V_y \eta \boldsymbol{\sigma}_z/c$, that

²To avoid confusion we emphasise that despite having four components, $\boldsymbol{\alpha}$ is *not* a relativistic four-vector.

depend on the lateral velocity V_y and the coefficient η . Such a *polarization mixing effect* vanishes for $k_z = 0$ in which case the incidence plane contains the y axis along which the slab moves and thus it remains a plane of mirror symmetry for the system assuring that s and p polarizations are independent. Conversely, when $k_z \neq 0$ and $k_{\parallel}^2 = V_y \omega k_y / c^2$, we have $\eta \rightarrow \infty$, and the polarization is now completely converted from one type to another between reference frames.

3. Scattering matrix

We consider the radiation pressure for the case where we have right and left moving waves in the free space regions, $x < -d/2$ (L), and $x > d/2$ (R), as shown in figure 1. In this case the slab is in lateral motion and the frequency, ω is conserved upon reflection and transmission.

In terms of the rest frame reflection and transmission coefficients of the slab (r'_q, t'_q), for a single incident plane wave the rate of energy lost from the electromagnetic field is proportional to $1 - |r'_q|^2 - |t'_q|^2$, which owing to the translational symmetry in y and z is also proportional to the lateral force on the slab. Meanwhile the force on the slab in the \hat{x} direction is proportional to $1 + |r'_q|^2 - |t'_q|^2$ [12]. These results can be generalized and written in matrix notation as follows (for example see [13])

$$\left\langle \frac{dP_M^\mu}{dt'} \right\rangle = \frac{\epsilon_0 A' c^2 |k'_x|}{2\omega'^2} \boldsymbol{\alpha}'_{\text{IN}} \begin{pmatrix} (\mathbb{1}_4 - \mathbf{S}'^\dagger \mathbf{S}') \omega' / c \\ (\mathbf{R} - \mathbf{S}'^\dagger \mathbf{R} \mathbf{S}') |k'_x| \\ (\mathbb{1}_4 - \mathbf{S}'^\dagger \mathbf{S}') k_y \\ (\mathbb{1}_4 - \mathbf{S}'^\dagger \mathbf{S}') k_z \end{pmatrix} \boldsymbol{\alpha}'_{\text{IN}}, \quad (9)$$

where $\mathbf{R} = \boldsymbol{\sigma}_z \oplus \boldsymbol{\sigma}_z$, A' is the cross-sectional area of the beam of radiation as seen in the rest frame of the slab, and the triangular brackets indicate that we have dropped any rapidly oscillating interference terms from the force. Equation (9) can be verified using (1–2), and calculating the energy momentum tensor of the electromagnetic field, and from this the rest frame four-force as in [3, 12]. The incoming field amplitudes multiply the matrices inside the four-vector, and are written as, $\boldsymbol{\alpha}'_{\text{IN}} = (\alpha'_{1\text{L}}^{(+)}, \alpha'_{1\text{R}}^{(-)}, \alpha'_{2\text{L}}^{(+)}, \alpha'_{2\text{R}}^{(-)})$. The outgoing ones are $\boldsymbol{\alpha}'_{\text{OUT}} = (\alpha'_{1\text{R}}^{(+)}, \alpha'_{1\text{L}}^{(-)}, \alpha'_{2\text{R}}^{(+)}, \alpha'_{2\text{L}}^{(-)})$, and in the rest frame the relationship between the two is given by the scattering matrix, $\mathbf{S}'(\omega', \mathbf{k}'^{(\pm)})$: $\boldsymbol{\alpha}'_{\text{OUT}} = \mathbf{S}' \cdot \boldsymbol{\alpha}'_{\text{IN}}$. We assume a medium that does not mix s and p polarizations when at rest, so that the rest frame scattering matrix reduces to a direct sum, $\mathbf{S}' = \mathbf{S}'_{11} \oplus \mathbf{S}'_{22}$, where

$$\mathbf{S}'_{qq} = \begin{pmatrix} t'_q & r'_q \\ r'_q & t'_q \end{pmatrix} \quad (10)$$

Once \mathbf{S}' is known this is equivalent to an exact solution of Maxwell's equations with the proper boundary conditions [14].

Performing a Lorentz transformation of (9) into the laboratory frame, where the slab is in motion, and applying the transformation of the field amplitudes in terms of (8) we find the following four-force in terms of laboratory frame field amplitudes,

$$\left\langle \frac{dP_M^\mu}{dt} \right\rangle = \frac{\epsilon_0 A c^2 |k_x|}{2\omega^2} \alpha_{\text{IN}}^\dagger \begin{pmatrix} (\mathbb{1}_4 - \tilde{\mathbf{S}}^\dagger \tilde{\mathbf{S}}) \omega/c \\ (\mathbf{R} - \tilde{\mathbf{S}}^\dagger \mathbf{R} \tilde{\mathbf{S}}) |k_x| \\ (\mathbb{1}_4 - \tilde{\mathbf{S}}^\dagger \tilde{\mathbf{S}}) k_y \\ (\mathbb{1}_4 - \tilde{\mathbf{S}}^\dagger \tilde{\mathbf{S}}) k_z \end{pmatrix} \alpha_{\text{IN}}, \quad (11)$$

where $A = A'/\gamma$. In (11), the effective laboratory frame scattering matrix is given by $\tilde{\mathbf{S}} = \mathbf{M}^\dagger \mathbf{S}' \mathbf{M}$, which is a 4×4 matrix with all entries generally non-zero.

$$\tilde{\mathbf{S}} = \mathbf{M}^\dagger (\mathbf{S}'_{11} \oplus \mathbf{S}'_{22}) \mathbf{M} = \frac{1}{1 + \frac{\eta^2 V_y^2}{c^2}} \begin{pmatrix} \mathbf{S}'_{11} + \left(\frac{\eta V_y}{c}\right)^2 \sigma_z \mathbf{S}'_{22} \sigma_z & \frac{\eta V_y}{c} (\mathbf{S}'_{11} \sigma_z - \sigma_z \mathbf{S}'_{22}) \\ \frac{\eta V_y}{c} (\sigma_z \mathbf{S}'_{11} - \mathbf{S}'_{22} \sigma_z) & \mathbf{S}'_{22} + \left(\frac{\eta V_y}{c}\right)^2 \sigma_z \mathbf{S}'_{11} \sigma_z \end{pmatrix} \quad (12)$$

The conclusion we can draw from comparing (11) with (9) is that a laterally moving medium responds akin to a stationary medium with a peculiar dependence on frequency and wavevector (i.e. the r'_q and t'_q contain the rest frame frequency and wave-vector), and reflection and transmission coefficients that are related to the rest frame reflection and transmission coefficients by a unitary transformation. At a frequency ω' where the material has negligible loss, $\mathbf{S}'^\dagger \mathbf{S}' = \mathbb{1}_4$, all components of the four-force, besides $\langle dP_M^1/dt \rangle$, vanish, consistent with energy and momentum conservation. In terms of the rest frame scattering matrices, \mathbf{S}'_{qq} , the effective laboratory frame scattering matrix takes the form (12), where the off-diagonal blocks linear in $(\eta V_y/c)$ are responsible for the polarization mixing effects.

4. Radiation pressure effects due to polarization mixing

The four-force in (11) along with (12) is an important result, as it embeds a new radiation pressure effect stemming from mixing of the s and p polarizations associated with moving frames. Two specific examples are now illustrated.

First, take the case of a plane polarized wave propagating in the direction $\hat{\mathbf{k}}^{(+)}$ onto the left of a laterally moving slab, the two input polarization amplitudes being $\alpha_{1L}^{(+)}$ and $\alpha_{2L}^{(+)}$. The resulting normalized³ normal ($\hat{\mathbf{x}}$) force is,

$$\left\langle \frac{d\tilde{P}_M^1}{dt} \right\rangle = \frac{c^2 k_x^2}{\omega^2 (1 + \eta^2 V_y^2 / c^2)} \left[1 + (|r'_1|^2 - |t'_1|^2) \left| \alpha_1 + \frac{\eta V_y}{c} \alpha_2 \right|^2 + (|r'_2|^2 - |t'_2|^2) \left| \alpha_2 - \frac{\eta V_y}{c} \alpha_1 \right|^2 \right] \quad (13)$$

³The tilde indicates that the force is in units of the incident average power $\epsilon_0 c (|\alpha_{1L}^{(+)}|^2 + |\alpha_{2L}^{(+)}|^2) A/2$ divided by c .

which to leading order in V_y/c is

$$\left\langle \frac{d\tilde{P}_M^1}{dt} \right\rangle \simeq \frac{c^2 k_x^2}{\omega^2} \left[1 + (|r'_1|^2 - |t'_1|^2) |\alpha_1|^2 + (|r'_2|^2 - |t'_2|^2) |\alpha_2|^2 + \frac{\eta V_y}{c} (|r_1|^2 - |t_1|^2 - |r_2|^2 + |t_2|^2) (\alpha_1 \alpha_2^* + \alpha_1^* \alpha_2) \right] \quad (14)$$

where we define $\alpha_i = \alpha_{iL}^{(+)} / \sqrt{|\alpha_{1L}^{(+)}|^2 + |\alpha_{2L}^{(+)}|^2}$. The last expression is correct to first order in V_y/c where $\eta \simeq |k_x|k_z/k_{\parallel}^2$, and the unprimed reflection and transmission coefficients depend on the laboratory frame frequency and wave-vector rather than the rest frame values. Other terms linear in V_y/c would appear upon expressing the primed reflection and transmission coefficients in terms of the laboratory frame quantities through the transformation of frequency and wave-vector components. Such an expansion would bring out familiar Doppler terms [3,4] that are independent of the polarization mixing terms proportional to $(\alpha_1^* \alpha_2 + c.c.)$ shown on the right hand side of (14). The normalized lateral ($\hat{\mathbf{y}}$) force, which vanishes for a lossless medium takes a similar form,

$$\left\langle \frac{d\tilde{P}_M^2}{dt} \right\rangle \simeq \frac{c^2 |k_x| k_y}{\omega^2} \left[1 - (|r'_1|^2 + |t'_1|^2) |\alpha_1|^2 - (|r'_2|^2 + |t'_2|^2) |\alpha_2|^2 + \frac{V_y \eta}{c} (|r_2|^2 + |t_2|^2 - |r_1|^2 - |t_1|^2) (\alpha_1 \alpha_2^* + \alpha_1^* \alpha_2) \right] \quad (15)$$

In general, polarization mixing contributions to the velocity dependent part of the force (14-15) are comparable to the Doppler terms⁴. Since they are proportional to $(\alpha_1^* \alpha_2 + c.c.)$, they vanish for unpolarized light, such as *e.g.* thermal radiation, where α_1 and α_2 do not have a definite mutual phase relation, and also for circularly polarized light ($\alpha_1 = 1/\sqrt{2}$, $\alpha_2 = \pm i/\sqrt{2}$). Even when $\eta \neq 0$, the polarization mixing effects vanish to linear order in V_y/c if in the lab frame the light is either purely *s* or purely *p* polarized, *yet* they survive and could be easily modulated or even flipped in sign by rotating the linear polarization when reflection and transmission for *s* and *p* polarizations are significantly different. In particular, for linearly polarized light with $\alpha_1 = \sin \varphi$ and $\alpha_2 = \cos \varphi$, corresponding to an electric field whose polarization vector makes an angle φ with $\hat{\mathbf{e}}_2^{(+)}$, one has $(\alpha_1^* \alpha_2 + c.c.) = \sin(2\varphi)$.

Secondly, we consider a situation where radiation pressure arises only when both the mixing coefficient η and the velocity do not vanish. Take two linearly polarized plane waves of equal intensity propagating in the direction $\hat{\mathbf{k}}^{(+)}$ and $\hat{\mathbf{k}}^{(-)}$, respectively onto the left and the right of a laterally moving slab. In much the same way as done above, the input field amplitudes may be chosen so that $\boldsymbol{\alpha}_{\text{IN}}^T = \mathcal{E}(e^{i\zeta_L} \sin(\varphi_L), e^{i\zeta_R} \sin(\varphi_R), e^{i\zeta_L} \cos(\varphi_L), e^{i\zeta_R} \cos(\varphi_R))$, where

⁴This holds for weakly dispersive media: whenever reflection and/or transmission have a strong dependence on frequency, such as in photonic bandgap media or close to an absorption line, the Doppler related effects can be amplified by many orders of magnitude [3,4]

$\Delta\zeta = \zeta_L - \zeta_R$ is the phase mismatch between the two input waves. Note that with our choice of polarizations the plane wave coming from the right and having $\varphi_R = \pi - \varphi_L$ is the mirror image of that coming from the left with respect to the $(z-y)$ plane of symmetry. Taking an average over $\Delta\zeta$ as appropriate for left and right incoming waves not having a definite mutual phase relation, the normal component of the force in this case can be obtained from (14) and the use of the mirror symmetry just described. In particular, for the specific choice $\varphi_R = \varphi_L = \varphi$ and retaining only terms linear in V_y/c , one has

$$\left\langle \frac{d\tilde{P}_M^1}{dt} \right\rangle \simeq \frac{2c|k_x|^2\eta V_y}{\omega^2} \sin(2\varphi)(|r_1|^2 - |t_1|^2 - |r_2|^2 + |t_2|^2) \quad (16)$$

This force, that is present even when equal incident intensities are used (in both polarization channels) on both sides of the slab, is entirely due to the mixing of polarizations in the transformation described by (8) and does not seem to have been recognised before. In addition, the force (16), which does not contain Doppler contributions, is typically of the same order as the velocity dependent radiation pressure stemming from the Doppler effect as mentioned in the introduction. Figure 2a shows the dependence of this force on the laboratory frame angle of incidence, θ when $\varphi = \pi/4$ for a non-dispersive, absorbing thin dielectric slab with thickness d comparable to the wavelength of the incident beam.

For small (but not zero) k_{\parallel} , η can become very large, and there is a large degree of polarization mixing. Although this is not relevant for ordinary materials, owing to the near degeneracy of s and p reflection and transmission coefficients at small angles of incidence, there are materials where the reflection and transmission coefficients remain significantly different close to normal incidence. This occurs e.g. in epsilon near zero metamaterials [15–17], and we plot in figure 2b the force on a slab with the same thickness but a refractive index three orders of magnitude smaller. Such an illustrative example shows more than an order of magnitude increase in the polarization mixing contribution to the velocity dependent force.

5. Conclusion

We have derived a relativistic transformation law, (7) to describe the change in polarization composition of an electromagnetic wave between inertial reference frames. This formula demonstrates that a laterally moving dielectric medium can mix polarizations, and that such effects are comparable in magnitude to those due to the Doppler shift. When applied to the theory of radiation pressure, this mixing of polarizations introduces new contributions to the force. In one example we have shown that a moving dielectric slab can experience a net force in the direction of the surface normal, (16) even when radiation of the same intensity and direction is incident onto both sides of the slab.

The configuration leading to (16) is of special interest as it enables one to observe *pure* polarization mixing contributions to the velocity dependence of radiation pressure. This, in

turn, can simply be tuned via the polarization angle, for instance it can be turned on and off by setting $\varphi_L = \pi/4$ and switching φ_R respectively to $\pi/4$ and $3\pi/4$. Such an ability can be important in the emerging field of nano-optomechanics [18], where small optical forces can be used to manipulate the centre of mass of mechanical oscillators of very light masses, or even atomic clouds [3]. In particular, it can allow to control the dynamics of a two-dimensional oscillator in which the motion along one axis (\hat{y} in our case) can be optomechanically coupled to that along the other one (\hat{x} in our case).

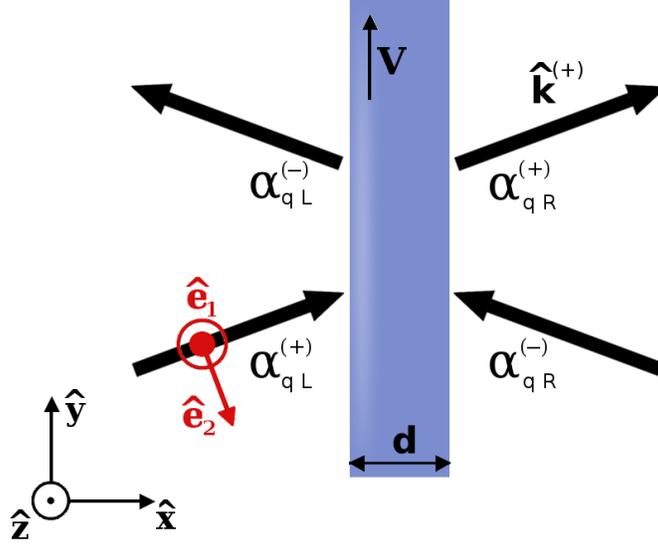

Fig. 1. The scattering matrix $\tilde{\mathbf{S}}$ in (11) connects the laboratory frame input $(\alpha_{qL}^{(+)}, \alpha_{qR}^{(-)})$ and output $(\alpha_{qL}^{(-)}, \alpha_{qR}^{(+)})$ amplitudes of fields scattering from a dielectric slab of thickness d and area $A = L_y L_z$ ($L_y, L_z \gg d$). The slab is centred at $x = 0$, moves laterally with velocity \mathbf{V} and with surface normal parallel to $\hat{\mathbf{x}}$. The s and p polarization unit vectors, respectively, $\hat{\mathbf{e}}_1$ and $\hat{\mathbf{e}}_2$ and unit wavevector $\hat{\mathbf{k}}^{(+)}$ are here displayed for the case of a plane wave propagating in the $(x - y)$ plane. More generally the unit vectors $\hat{\mathbf{e}}_1$ and $\hat{\mathbf{e}}_2^{(+)}$ lie in the $(\hat{\mathbf{z}} - \hat{\mathbf{y}})$ plane and in the incidence plane $(\hat{\mathbf{x}} - \hat{\mathbf{k}}_{\parallel})$ plane, respectively. Likewise for the incident wave-vector that is written as, $\mathbf{k} = k_x \hat{\mathbf{x}} + k_{\parallel} \hat{\mathbf{k}}_{\parallel} = (\omega/c)[\cos(\theta)\hat{\mathbf{x}} + \sin(\theta)(\sin(\chi)\hat{\mathbf{y}} + \cos(\chi)\hat{\mathbf{z}})]$ where θ is referred to as the angle of incidence.

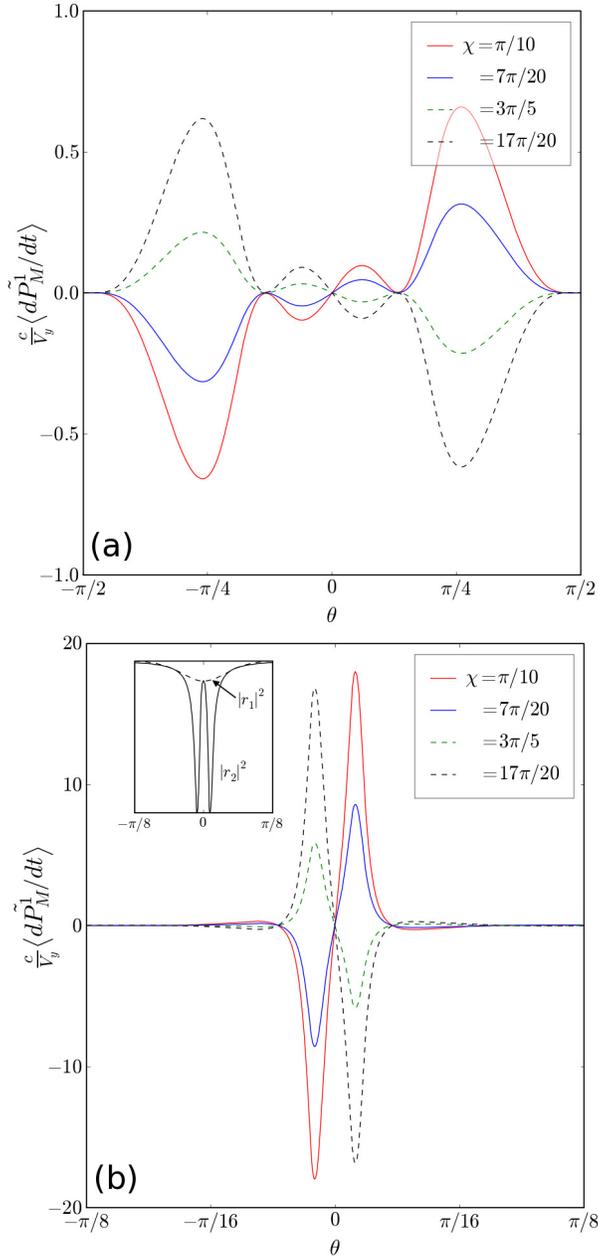

Fig. 2. (a) Normal force exerted by a light beam of frequency ω on a laterally moving dielectric slab of thickness $d = 10c/\omega$. The force, plotted as a function of the angle of incidence θ , is computed from (16) where the optical response parameters, r_i and t_i are evaluated using (a) $\epsilon = 5.0 + 0.001i$ and (b) $\epsilon = 0.001 + 0.001i$ and $\mu = 1$. The incident wave-vector is defined as in figure 1. Inset shows the s (dashed) and p (solid) reflection coefficients for such a slab. This calculation was performed using the reflection and transmission coefficients for a slab of arbitrary thickness [14].
