7	Impact of COVID-19 Restrictions on Mental Health and Physical Activity Among
8	LGBQAP and Heterosexual Adults

9

Structured Abstract

- 10 Introduction: We compared the impact of the COVID-19 lockdown on mental health (MH) and
- 11 physical activity (PA) between US adults who identify as lesbian, gay men, bisexual, queer,
- 12 asexual, and pansexual (LGBQAP) and heterosexual US adults.
- 13 Method: Participants completed online questionnaires to assess PA and MH.
- 14 **Results:** No difference in MH was identified between LGBQAP and heterosexual participants
- 15 prior to lockdown, however LGBQAP participants reported significantly worse mental health
- 16 during lockdown. No group differences were found in PA, but all participants exhibited a decline
- 17 in PA during lockdown.
- 18 Conclusion: This study highlights the differential impact of social restrictions on marginalized
- 19 populations.
- 20

44 susceptible than others to the attendant psychosocial consequences (Pfefferbaum & North, 2020).

45	Marginalized communities have been identified as "those excluded from mainstream
46	social, economic, educational, and/or cultural life" (Sevelius et al., 2020, p. 2009), including, but
47	not limited to groups that are excluded on the basis of race, gender identity, sexual orientation,
48	age, physical ability, language, and/or immigration status (Sevelius et al., 2020). One such
49	subgroup includes individuals who identify as lesbian, gay, bisexual, transgender, queer, and
50	other diverse sexual orientations and gender identities (LGBTQ+), who, despite well-
51	documented vulnerability to a number of social, health, and psychological risks, have received
52	minimal attention during the COVID-19 pandemic (Salerno et al., 2020).
53	Mental and physical health disparities have been documented between LGBTQ+ persons
54	and their heterosexual, cisgender counterparts (Gorczynki & Fasoli, 2020). Researchers have
55	reported increased prevalence of chronic diseases, substance abuse, anxiety, depression, and
56	suicide (Gorczynski & Fasoli, 2020). These disparities are likely a result of exposure to prejudice
57	and discrimination in the social environment, referred to as minority stress (Meyer, 2003), and
58	thus related to social inequalities, such as poorer access to healthcare and higher rates of poverty,
59	that disproportionately affect LGBTQ+ persons compared to heterosexual and cisgender peers
60	and may be intensified by the global pandemic (Salerno et al., 2020). For example, as a higher
61	percentage of LGBTQ+ individuals work in service industry jobs (40% compared to 20% of
62	heterosexuals), thus likely being at a higher risk of unemployment, loss of healthcare, and facing
63	greater financial distress as a result of lockdown (Salerno et al., 2020). As the pandemic
64	continues to impact societies the world over, it is important to find ways to improve or maintain
65	psychological health (Holmes et al., 2020), particularly among groups that are marginalized.
66	PA has been shown to protect both physical and mental health (Rebar et al., 2015) and
67	shows inverse associations with anxiety and depressive symptoms (McDowell et al., 2019;

69related stress and mitigate its detrimental effects on mental health and wellbeing. In addition, PA70is strongly associated with a reduced risk for severe COVID-19 outcomes, including71hospitalization, intensive care unit admission, and death, even after controlling for other risk72factors (Sallis et al., 2021). However, the restrictions and social distancing measures adopted in73response to the COVID-19 pandemic left limited opportunities for planned PA, as most sports74facilities, gyms, and public swimming pools were closed. Likewise, opportunities for unplanned75PA diminished with the closure of parks and playgrounds and greater reliance on virtual76communication for activities such as work, education, and shopping.77Tison et al. (2020) examined the effect of COVID-19-related lockdown on daily step78countries, there was a 27.3% decrease in mean daily step counts after 30 days of79confinement when compared to prepandemic data. Likewise, an analysis of Fitbit's user data81indicated a 5 20% reduction in total steps worldwide during the early stages of the pandemic82(Cheval et al., 2020; Dunton et al., 2020), and resistance-based exercise (Faulkner et al., 2020).84is important to note that some groups have been able to sustain, or even increase, PA behavior87is important to note that some groups have been able to sustain, or even all metal health88been more physically active during COVID-19 restrictions have better overall mental health89idac et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and80exe	68	Schuch et al., 2018). Therefore, engaging in PA might help people in coping with COVID-19-
 hospitalization, intensive care unit admission, and death, even after controlling for other risk factors (Sallis et al., 2021). However, the restrictions and social distancing measures adopted in response to the COVID-19 pandemic left limited opportunities for planned PA, as most sports facilities, gyms, and public swimming pools were closed. Likewise, opportunities for unplanned PA diminished with the closure of parks and playgrounds and greater reliance on virtual communication for activities such as work, education, and shopping. Tison et al. (2020) examined the effect of COVID-19-related lockdown on daily step counts using de-identified data collected via a smartphone app. Across 455,404 app users from 187 countries, there was a 27.3% decrease in mean daily step counts after 30 days of confinement when compared to prepandemic data. Likewise, an analysis of Fitbit's user data indicated a 5 -20% reduction in total steps worldwide during the early stages of the pandemic (Fitbit Inc., 2020). A number of other studies – primarily those collecting self-report data – have indicated significant decreases in moderate-to-vigorous PA (Dunton et al., 2020), walking time (Cheval et al., 2020; Dunton et al., 2020), and resistance-based exercise (Faulkner et al., 2020). Despite overwhelming evidence of reductions in PA during the COVID-19 pandemic, it is important to note that some groups have been able to sustain, or even increase, PA behavior (Brand et al., 2020; Nienhuis & Lesser, 2020). Notably, it appears that individuals who have been more physically active during COVID-19 restrictions have better overall mental health (Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and 	69	related stress and mitigate its detrimental effects on mental health and wellbeing. In addition, PA
72factors (Sallis et al., 2021). However, the restrictions and social distancing measures adopted in73response to the COVID-19 pandemic left limited opportunities for planned PA, as most sports74facilities, gyms, and public swimming pools were closed. Likewise, opportunities for unplanned75PA diminished with the closure of parks and playgrounds and greater reliance on virtual76communication for activities such as work, education, and shopping.77Tison et al. (2020) examined the effect of COVID-19-related lockdown on daily step78countries, there was a 27.3% decrease in mean daily step counts after 30 days of79confinement when compared to prepandemic data. Likewise, an analysis of Fitbit's user data81indicated a 5–20% reduction in total steps worldwide during the early stages of the pandemic82(Fitbit Inc., 2020). A number of other studies – primarily those collecting self-report data – have83indicated significant decreases in moderate-to-vigorous PA (Dunton et al., 2020), walking time84(Cheval et al., 2020; Dunton et al., 2020), and resistance-based exercise (Faulkner et al., 2020).85Despite overwhelming evidence of reductions in PA during the COVID-19 pandemic, it86is important to note that some groups have been able to sustain, or even increase, PA behavior87(Brand et al., 2020; Nienhuis & Lesser, 2020). Notably, it appears that individuals who have88been more physically active during COVID-19 restrictions have better overall mental health89(Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and	70	is strongly associated with a reduced risk for severe COVID-19 outcomes, including

For example, those who report a negative change (i.e., decrease) in PA and 	80	confinement when compared to prepandemic data. Likewise, an analysis of Fitbit's user data
 indicated significant decreases in moderate-to-vigorous PA (Dunton et al., 2020), walking time (Cheval et al., 2020; Dunton et al., 2020), and resistance-based exercise (Faulkner et al., 2020). Despite overwhelming evidence of reductions in PA during the COVID-19 pandemic, it is important to note that some groups have been able to sustain, or even increase, PA behavior (Brand et al., 2020; Nienhuis & Lesser, 2020). Notably, it appears that individuals who have been more physically active during COVID-19 restrictions have better overall mental health (Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and 	81	indicated a 5–20% reduction in total steps worldwide during the early stages of the pandemic
 (Cheval et al., 2020; Dunton et al., 2020), and resistance-based exercise (Faulkner et al., 2020). Despite overwhelming evidence of reductions in PA during the COVID-19 pandemic, it is important to note that some groups have been able to sustain, or even increase, PA behavior (Brand et al., 2020; Nienhuis & Lesser, 2020). Notably, it appears that individuals who have been more physically active during COVID-19 restrictions have better overall mental health (Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and 	82	(Fitbit Inc., 2020). A number of other studies – primarily those collecting self-report data – have
 Despite overwhelming evidence of reductions in PA during the COVID-19 pandemic, it is important to note that some groups have been able to sustain, or even increase, PA behavior (Brand et al., 2020; Nienhuis & Lesser, 2020). Notably, it appears that individuals who have been more physically active during COVID-19 restrictions have better overall mental health (Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and 	83	indicated significant decreases in moderate-to-vigorous PA (Dunton et al., 2020), walking time
 is important to note that some groups have been able to sustain, or even increase, PA behavior (Brand et al., 2020; Nienhuis & Lesser, 2020). Notably, it appears that individuals who have been more physically active during COVID-19 restrictions have better overall mental health (Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and 	84	(Cheval et al., 2020; Dunton et al., 2020), and resistance-based exercise (Faulkner et al., 2020).
 (Brand et al., 2020; Nienhuis & Lesser, 2020). Notably, it appears that individuals who have been more physically active during COVID-19 restrictions have better overall mental health (Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and 	85	Despite overwhelming evidence of reductions in PA during the COVID-19 pandemic, it
 been more physically active during COVID-19 restrictions have better overall mental health (Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and 	86	is important to note that some groups have been able to sustain, or even increase, PA behavior
(Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and	87	(Brand et al., 2020; Nienhuis & Lesser, 2020). Notably, it appears that individuals who have
	88	been more physically active during COVID-19 restrictions have better overall mental health
90 exercise habits from prior to during COVID-19, also report poorer mental health (Faulkner et al.,	89	(Jacob et al., 2020). For example, those who report a negative change (i.e., decrease) in PA and
	90	exercise habits from prior to during COVID-19, also report poorer mental health (Faulkner et al.,

91	2020), increased loneliness and stress (Meyer et al., 2020), lower social, emotional and
92	psychological wellbeing, and higher generalized anxiety (Nienhuis & Lesser, 2020). Although
93	the evidence is limited by (necessarily) cross-sectional approaches to data collection, it indicates
94	that the known association between PA and superior mental health status (McDowell et al., 2019;
95	Schuch et al., 2018) can be sustained during times of stress or crisis (Cheval et al., 2020).
96	Generally, LGBTQ+ communities have been understudied in the realm of PA
97	(Gorcyznski & Brittain, 2016), yet warrant special attention given the health disparities that
98	affect its members. Evidence from the few studies relating to PA has been equivocal. For
99	example, compared to heterosexual youth, LGB youth exhibit lower participation rates in terms
100	of 60 min of moderate-to-vigorous PA each week (lesbian/gay = 19%; bisexual = 17%
101	heterosexual = 25%; Mereish & Poteat, 2015). This discrepancy has been attributed to
102	microaggressions, discrimination, and harassment experienced in sport and PA during formative
103	years (Herrick & Duncan, 2018). Furthermore, Herrick et al. (2021) found that proximal
104	minority stressors were negatively associated with the satisfaction of psychological needs in PA
105	settings among LGBTQ+ adults. The lack of satisfaction, in turn, undermined the motivation to
106	engage in PA.

In contrast, other researchers have indicated that PA participation among adult lesbians, gay men, and bisexual men and women is similar or greater than individuals who identify as heterosexual (Boehmer et al., 2012; VanKim et al., 2017). More specifically, VanKim et al. (2017) reported that lesbian and bisexual women reported higher MET-hours/week in aerobic activity compared to heterosexual women. Bisexual women, as well as gay and bisexual men, report higher levels of muscle strengthening activity when compared to their heterosexual counterparts (Boehmer et al., 2012). LGBTQ+ adults often seek safe and inclusive environments to engage in sport and PA such as queer-friendly gyms (Herrick & Duncan, 2018), competitive sports teams (Willis, 2015), or recreational leagues and club teams (Calwood & Smith, 2019). Lockdown restrictions and social distancing measures due to COVID-19 likely impact the way in which LGBTQ+ adults engage in PA. The combined impact of social restrictions and limited access to LGBTQ+ inclusive spaces for leisure, PA, and sport may, therefore, have a disproportionately negative impact on LGBTQ+ individuals.

121 **Purpose and Hypotheses**

122 It is evident that COVID-19 has disproportionately impacted marginalized communities in the United States and across the world. Nonetheless, little is known about the ramifications for 123 124 LGBTQ+ communities, bearing in mind that this subgroup of the population is already subject to 125 higher levels of disparity in mental and physical health. Accordingly, we investigated the impact of the United States COVID-19 lockdown on mental health and PA among individuals who 126 127 identify as lesbian, bisexual, gay, queer, and other diverse sexual orientations compared to heterosexual identifying participants. We tested two hypotheses: H_1 Participants representing a 128 diverse array of sexual orientations would report a larger decline in mental health from prior-to-129 130 lockdown to during lockdown when compared to heterosexual participants; H_2 Participants 131 representing a diverse array of sexual orientations would report a larger decrease in planned and 132 unplanned PA from prior-to-lockdown to during lockdown when compared to heterosexual 133 participants.

134

Method

Some of the data from the present study are drawn from a larger study examining PA,
sedentary behavior, and mental health across four Western nations (Author citation, in press).

137 We assessed mental health and PA during the United States' initial COVID-19 lockdown.

138 Participants were also asked to answer questions about their mental health and PA prior to

139 lockdown by use of a retrospective frame.

140 **Participants**

Overall, 585 individuals residing in the United States participated in this study, including 141 142 452 (77%) women, 130 (22%) men, two (< 1%) individuals who identified as "other" and one (< 1%) person who "preferred not to say". Participants were all at least 18 years old and their age 143 range was 18–92 years (M = 37.6, SD = 15.8). Most participants identified their sexual 144 145 orientation as heterosexual (n = 533, 91%). Individuals also identified as lesbian (n = 19, 3%), bisexual (n = 21, 4%), gay man (n = 4, 1%), queer (n = 2, <1%), asexual (n = 3, <1%), or 146 pansexual (n = 3, 1%). For the purposes of the current study, individuals who identified as 147 148 lesbian, bisexual, gay man, queer, asexual, or pansexual were collapsed into a single category (n = 52, 9%). We labeled the category LGBQAP to recognize all sexual orientations indicated by 149 participants. Initial comparisons were made between LGBQAP and heterosexual participants on 150 151 key anthropometric indices. No significant mean differences were found in age, height, weight, and BMI. Additional descriptive data pertaining to the sample can be found in Table 1. 152

153 Instrumentation

154 Planned and Unplanned Physical Activity

The Brunel Lifestyle Physical Activity Questionnaire (BLPAQ; Karageorghis et al., 2005) was used to assess participants' planned and unplanned PA prior to and during the COVID-19 lockdown. Planned PA was defined as, "...any activity that is scheduled into your daily routine, which may enhance your health, fitness or wellbeing." Examples included brisk walking, jogging, cycling, and gardening. Unplanned PA was defined as any other form of PA

160	"excluding pre-planned physical activity" and was assessed with items such as, "In general, how
161	physically demanding has your job or day-to-day activities been during the social distancing
162	period?" Participants were asked to respond to the nine items in this scale (six for planned PA
163	and three for unplanned PA) using a 5-point, continuous-closed numerical scale (e.g., $1 = Not$ at
164	all, $5 = Highly$). Reliability and validity of the BLPAQ scores have been demonstrated in
165	previous studies (Vencato et al., 2017a; Vencato et al., 2017b). In the present sample, internal
166	consistency estimates for planned PA were .91 (prior to lockdown) and .93 during lockdown).
167	Alpha estimates were lower for the 3-item unplanned PA scale (prior to lockdown = .55, during
168	lockdown = .65). Cronbach's alpha is often smaller among scales with fewer items (Loewenthal
169	& Lewis, 2020). The retrospective nature of measures for behaviors prior to lockdown may also
170	have served to reduce internal consistency.

171 Mental Health

The General Health Questionnaire-12 (GHQ-12; Goldberg & Williams, 1988) was used to assess participants' mental health prior to and during the COVID-19 lockdown. This 12-item scale includes items such as, "Have you recently been able to enjoy your normal day-to-day activities?" to which participants respond using a 4-point scale (e.g., $0 = More \ so \ than \ usual$ to 3 $= Much \ less \ than \ usual$). Adequate reliability and validity evidence has been reported in previous studies (see Hardy et al., 1999). In the present sample, the internal consistency estimate was .86 for the retrospective, prior to lockdown, administration, and .91 during lockdown.

179 **Procedures**

Procedures for the protection of human research participants were reviewed and accepted
by an institutional ethics review board. Data were collected via Qualtrics (Provo, UT) at one time
point using a self-report, survey-based approach. Individuals were invited to take part in the

study and provided with direct access to the online survey via recruitment posts on social media (e.g., Facebook, Instagram, and Twitter) and direct email communication. Collection occurred in the early phases of the COVID-19 pandemic in the United States (April 24–May 18, 2020). The timing of the collection captured the initial, and possibly most dramatic, change to people's daily routines related to various pandemic restrictions. Participants provided informed consent and the survey took ~20 min to complete.

189 Statistical Analysis

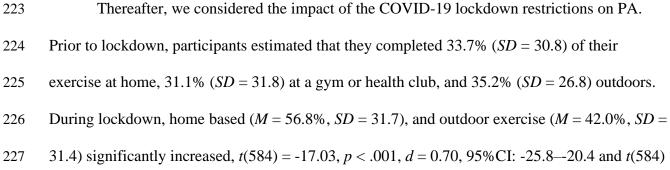

The Statistical Package for the Social Sciences (SPSS) v26.0 (Armonk, NY) was used to 190 191 conduct the analyses described herein. Prior to the analyses, data were screened for missing data, outliers, normality within each cell of the analysis, and other assumptions that underlie analysis 192 193 of variance (ANOVA). Descriptive statistics were conducted to evaluate the demographic 194 variables, COVID-19 status, and PA both prior to and during COVID-19 lockdown. A 2 (Time) 195 \times 2 (Sexual Orientation) mixed-model (within-between) ANOVA was conducted to examine 196 mental health, and a 2 (Time) \times 2 (Sexual Orientation) mixed-model (within-between) 197 MANOVA was conducted to examine planned and unplanned PA. Simple effects tests and Bonferroni-adjusted post hoc comparisons were used as appropriate. Additionally, Pearson 198 199 product-moment correlations were computed to examine the relationship between mental health 200 and PA for both LGBQAP and heterosexual participants. Alpha was set at .05 for all analyses, 201 unless otherwise specified.

202

Results

The survey was opened 1,858 times and 1,153 participants met the initial criteria of
residing in the United States, being ≥18 years old and able to complete the survey in English.
Participants who did not complete the survey in its entirety were removed prior to the analyses,

206	resulting in 595 usable survey responses. Ten participants were removed because they did not
207	identify their sexual orientation. Consequently, 585 surveys were deemed suitable for analysis.
208	Data were inspected for univariate outliers exhibiting <i>z</i> -scores $> \pm 3.29$. Outlying scores were
209	reduced to the highest or lowest value not considered an outlier (Tabachnick & Fidell, 2019).
210	The normality of dependent variables was then assessed and all were negatively skewed (planned
211	PA at both time periods) or positively skewed (unplanned PA and mental health at both time
212	periods; all $ps < .001$). Given the relative robustness of (M)ANOVA in the case of skewed
213	distributions (Tabachnick & Fidell, 2019), data transformations were not applied.
214	To address our first hypothesis, we compared the impact of lockdown on the mental
215	health of LGBQAP vs. heterosexual participants. A 2 (Time) \times 2 (Sexual Orientation) ANOVA
216	revealed a significant two-way interaction, $F(1, 583) = 6.19$, $p = .013$, $\eta_p^2 = .01$. A simple effects
217	test was conducted to analyze the interaction. No significant mean difference was found between
218	LGBQAP ($M = 11.7$, $SD = 4.9$) and heterosexual participants' ($M = 11.1$, $SD = 4.2$) retrospective
219	responses to the GHQ-12, <i>t</i> (583) = -0.97, <i>p</i> = .331, <i>d</i> = .14, 95%CI: -1.8–0.6. However, during
220	lockdown, LGBQAP participants ($M = 19.6$, $SD = 6.9$) reported significantly higher GHQ-12
221	scores, indicating poorer mental health when compared to heterosexuals ($M = 16.4$, $SD = 7.2$),
222	t(583) = -3.06, p = .002, d = .45, 95%CI: -5.2–-1.1.
223	Thereafter, we considered the impact of the COVID 10 lockdown restrictions on PA

228	= -5.58, $p < .001$, $d = 0.23$, 95%CI: -9.2–-4.4, respectively. Gym or health club use significantly
229	decreased to 1.3% ($SD = 8.4\%$), $t(584) = 22.72$, $p < .001$, $d = 1.25$, 95%CI: 27.3–32.5.
230	We computed a mixed-model MANOVA to determine whether PA frequency (planned
231	and unplanned) differed between LGBQAP and heterosexual participants. No Time \times Sexual
232	Orientation interaction emerged, Wilks's $\Lambda = 1.00$, $F(2, 582) = 1.55$, $p = .212$, $\eta_p^2 = .00$.
233	Additionally, no significant mean differences were found in PA between LGBQAP and
234	heterosexual participants, Wilks's $\Lambda = 1.00$, $F(2, 582) = 0.24$, $p = .79$, $\eta_p^2 = .00$. Nonetheless, a
235	significant main effect of time emerged, Wilks's $\Lambda = .92$, $F(2, 582) = 25.50$, $p < .001$, $\eta_p^2 = .08$.
236	Participants reported higher planned PA prior to lockdown ($M = 3.8$, $SD = 1.0$) compared to
237	during (<i>M</i> = 3.5, <i>SD</i> = 1.1), <i>F</i> (1, 583), = 17.13, <i>p</i> < .001, <i>d</i> = 0.28, 95% CI: 0.16–0.46. Similarly,
238	unplanned PA was significantly higher prior to lockdown ($M = 2.4$, $SD = 0.7$) compared to
220	
239	during $(M = 2.1, SD = 0.8)$, $F(1, 583) = 46.91$, $p < .001$, $d = 0.38$, 95% CI: .28–.50.
239 240	during ($M = 2.1, SD = 0.8$), $F(1, 583) = 46.91, p < .001, d = 0.38, 95\%C1$: .28–.50. We ran correlation analyses between mental health and PA in both groups of participants,
240	We ran correlation analyses between mental health and PA in both groups of participants,

As unplanned PA increased, GHQ-12 scores decreased (i.e., mental health was improved). This pattern of relationships remained consistent during lockdown ($r = .13$, $p =$.377 and $r = .36$, $p = .008$, respectively). For heterosexual participants prior to lockdown, a
 240 241 242 243 244 245 246 247 	We ran correlation analyses between mental health and PA in both groups of participants, both prior to and during lockdown. For LGBQAP individuals prior to lockdown, no significant linear relationship was found between mental health and planned PA ($r = .00$, $p = .984$), but a marginally significant negative relationship was found between mental health and unplanned PA ($r = .28$, $p = .046$). As unplanned PA increased, GHQ-12 scores decreased (i.e., mental health was improved). This pattern of relationships remained consistent during lockdown ($r = .13$, $p =$.377 and $r =36$, $p = .008$, respectively). For heterosexual participants prior to lockdown, a weak but significant relationship was found between mental health and planned PA ($r =14$, $p =$

p < .001) and unplanned PA (r = -.22, p < .001) in heterosexual participants.

251

Discussion

The sudden onset of the COVID-19 pandemic and the restrictions set in place to combat 252 the virus have disrupted daily activities, leading to changes in mental and physical wellbeing. 253 While the global pandemic has disaffected all segments of society, marginalized groups have 254 255 experienced a substantially greater burden. The purpose of the present study was to examine the 256 impact of the COVID-19 lockdown on mental health and PA among individuals who identify as lesbian, bisexual, gay, queer, and other diverse sexual orientations compared to those who 257 258 identify as heterosexual. 259 To address our first hypothesis (H_1) , we found that while all participants reported a decrease in mental health during lockdown, this drop was significantly larger for LGBQAP 260 participants. This finding is consistent with how other marginalized groups have been afflicted 261 262 by the COVID-19 pandemic. For example, researchers have reported mental health disparities as a consequence of race and ethnicity (McKnight et al., 2021) as well as gender (Gausman & 263 264 Langer, 2020). Thus far, sexual orientation has been largely ignored. The present findings begin to fill a gap in the literature that will serve as a bridge toward appropriate mental health support 265

for LGBQAP persons (Gorcyznisk & Fasoli, 2020). As PA has a potentially protective effect in
regard to decrements in mental health, we explored how both groups engaged in PA prior to and
during lockdown, as well the relationships between mental health and PA.

Prior to the COVID-19 lockdown, participants in the current study reported a fair level of PA. More specifically, the BLPAQ scores illustrate that, relative to the normative values for planned and unplanned PA reported by Karageorghis et al. (2005), both groups of present participants exceeded these pre-lockdown. Moreover, PA levels on the whole were indicative of a frequency, duration, and intensity of weekly activity that is a small degree below what is recommended by the ACSM (2018). The during lockdown scores show a decrement in PA that is
of an equal measure in the planned and unplanned dimensions. The drop shifts the weekly
frequency, duration, and intensity of activity to a moderate degree below ACMS
recommendations.

The levels of PA engagement between LGBQAP and heterosexual participants were 278 279 similar, consistent with previous research that has demonstrated similar PA participation rates between LGB and heterosexual individuals (Boehmer et al., 2012; VanKim et al., 2017). We 280 observed a small but significant decrease in both planned and unplanned PA across the study 281 282 sample during the initial COVID-19 lockdown, which is consistent with other researchers (e.g., Cheval et al., 2020; Dunton et al., 2020; Tison et al., 2020) who reported decreases in PA as a 283 result of lockdown restrictions, but did not distinguish between planned and unplanned PA. The 284 magnitude of the drop in planned and unplanned PA was broadly analogous to that reported in 285 other Western nations over the same time period (e.g., France; Guérin et al., 2021). No 286 287 differences in PA habits, planned or unplanned, were observed between LGBOAP and heterosexual individuals during lockdown. This finding is contrary to our expectation that 288 COVID-19 restrictions would have a more negative impact on LGBQAP participants (H_2) . It 289 290 also contrasts with initial findings pertaining to other marginalized groups; for example, racial differences have been reported during but not prior to lockdown for exercise frequency (Bann et 291 al., 2020). We did find that PA positively contributed to mental health in both groups. During 292 293 lockdown, both planned and unplanned PA were weakly, but significantly, associated with mental health in heterosexual respondents. For LGBQAP participants, a moderate association 294 295 was found between mental health and the frequency of unplanned PA.

296 While only minimal differences were found in frequency of PA, participant responses reflected a notable shift in where PA took place. Certainly, access to gyms and other organized 297 PA venues was limited or entirely unavailable given the imposition of social distancing and 298 299 quarantine restrictions. Accordingly, it is unsurprising that the percentage of time spent 300 exercising in a gym or health club exhibited a dramatic decline (from 31.1% to 1.3%). This was 301 offset somewhat by an increase in time spent exercising at home and in outdoor spaces during lockdown. This change in exercise environment would have forced many individuals into 302 modifying current exercise habits and/or adopting new PA behaviors. Albeit these changes did 303 304 not result in a difference in PA between groups based on sexual orientation, it is possible that the changes in the social facets of PA affected these groups differentially. For example, given that 305 306 individuals. Who identify as LGBQAP would already have been more likely to avoid traditional 307 gym settings (Herrick & Duncan, 2018), unplanned PA could be more conducive to LGBQAP participation, thus resulting in a stronger link with mental health than planned PA. 308 Social restrictions imposed in March 2020 across the United States to "flatten the curve" 309 310 such as social distancing, self-isolation, and quarantine had the likely consequence of detaching many LGBQAP individuals from their PA and social networks. While Herrick and Duncan 311 312 (2018) noted that sport and PA are generally in the heterosexual domain, increased opportunities 313 to participate in queer-inclusive spaces exist that encourage PA participation in LGBTQ+ 314 communities. Inclusive spaces for sport and PA offer a sense of community and belonging 315 (Calwood & Smith, 2019), promote collective self-efficacy, and foster a sense of selfempowerment (Krane et al., 2005). Inclusive competitive recreational teams (e.g., gay male 316 317 soccer team; Willis, 2015) or leagues also provide a safe space for individuals to participate in

318 sport and socialize with other LGBTQ+ individuals or allies. During lockdown, as most gyms

closed and athletic teams were unable to compete, individuals shifted their PA primarily to thehome and outdoors, likely reducing more social forms of PA.

In addition to PA restrictions, individuals were no longer able to access some LGBTO+-321 inclusive spaces like gay bars or teen and community centers that can foster social bonds 322 (Anderson & Knee, 2020). Similarly, COVID-19 restrictions limited access to large community 323 324 events like Pride Parades, commonly held in the month of June (Haynes, 2020). Many LGBTQ+ adolescents may have been forced to spend more time in home environments where they are not 325 accepted or supported, or where they may have not disclosed their sexual orientation or gender 326 327 identity (Salerno et al., 2020). Older members of LGBTQ+ communities are twice as likely to live alone when compared with their heterosexual counterparts, and 3–4 times less likely to have 328 329 children, making them more vulnerable to social isolation and its potentially deleterious 330 consequences (Yang et al., 2018). In the current study, a greater percentage of LGBQAP participants identified as single (63.5% compared to 46.2% of heterosexual participants) and 331 332 fewer indicated that had children living at home with them (12% compared to 30% of heterosexual participants). Thus, it is not surprising that the imposed restrictions had a marked 333 effect on the mental health of LGBQAP participants. 334

335 Implications of the Present Findings

Lessons learned from the present study can be applied to benefit LGBTQ+ communities for future disturbances to social norms of this nature. Health, wellness, and sport professionals who work with LGBQAP clients/patients/athletes should take note of the differential impact on mental health and adjust their level of support as necessary during such times of social isolation. Additional digital check-ins or increased scheduling of virtual or socially-distanced gatherings may be warranted to maintain a sense of social connectedness (e.g., Perone et al., 2020). Practitioners might also discuss how maintaining PA habits at home or outdoors can support mental health. Individuals and companies that provide digital exercise instruction might consider engaging the LGBQAP population, offering inclusive programming that is directly targeted at them. Finally, exercise/sport professionals should be prepared to refer any individual who is experiencing mental health challenges to an appropriate health professional.

347 Suggestions for Future Research

Future researchers might address the long-term effects of lockdown on LGBTQ+ 348 communities. Negative impacts on mental health have likely continued past the end of the first 349 350 lockdown (approximately May 25 2020, varying by state), as many states continue to encourage or mandate social-distancing measures that inhibit social gatherings, until COVID-19 vaccines 351 352 are widely administered. Surveillance and interventions aimed at maintaining and improving 353 mental health are particularly important in this subgroup of the population. Researchers should also continue to examine LGBQAP persons' access to mental healthcare against a backdrop of a 354 355 highly increased need among the general population.

356 Limitations of the Present Study

We acknowledge that some aspects of the research design limit generalizability of our 357 358 findings. Retrospective assessment of mental health and PA in relation to the pre-lockdown 359 period could have introduced recall errors and biases, potentially represented by greater 360 variability in those assessments. Caution should be exercised when considering the retrospective 361 analysis. In addition, the disproportionate sample sizes of heterosexual and LGBQAP adults may have influenced the analysis and outcomes of this study. For example, while the LGBQAP 362 363 participant representation in this study is similar to national estimates and reflects other work 364 examining PA in this population (e.g., Boehmer et al., 2012; VanKim et al., 2012), we were

unable to control for other factors associated with PA participation, such as gender and education
level, due to the uneven subsamples within the overall sample. We acknowledge that the
relationship between mental health and PA is highly complex and nuanced, but offer the present
findings as a point of origin in furthering understanding of the impact of the COVID-19
pandemic.

370 In order to allow for comparisons, we condensed individuals who identify as LGBQAP into a single group. In doing so, we risk homogenizing a complex community. Further, our data 371 do not represent transgender adults or other diverse gender identities. As transgender individuals 372 373 tend to report lower levels of PA (Jones et al., 2017) and disproportionality greater negative 374 mental health outcomes (James et al., 2016), it is critical that gender identity also be considered when considering the impact of lockdown on mental and physical health in marginalized groups. 375 376 Moreover, as Herrick and Duncan (2018) noted, intersectionality should be accounted for when considering PA participation among the LGBTQ+ population. Our sample was primarily white 377 and of a middle-class background. The experiences of LGBTQ+ individuals who also identify as 378 379 Black, Indigenous, and people of color (BIPOC) are therefore underrepresented. We recognize that the study findings and associated limitations are specific to the COVID-19 context. 380 381 However, the limitations acknowledged should be addressed in future mental and physical wellbeing research involving marginalized groups as they appear to be a recurring issue within 382 383 the extant literature (Gorcyznski & Brittain, 2016). 384 Conclusions

The present findings add to a rapidly growing literature that serves to increase understanding of the wide-ranging psychological and physical impact of COVID-19. While the drastic social restrictions of COVID-19 touched all parts of society, the isolating impact of such

- 388 measures will vary for different groups within society. Our findings indicate that the COVID-19
- 389 lockdown had a more negative impact on LGBQAP individuals. This is particularly concerning
- 390 given that such individuals are already more likely to struggle with mental health concerns and
- 391 have poorer access to healthcare.
