Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

Abstract

Comprehensive experimental and density functional theory simulations have been performed for the enhanced photoelectrochemical performance of gamma irradiated g-C₃N₄ and its heterojunction with BiVO₄. The structure and morphology of g-C₃N₄@BiVO₄ as a heterojunction were analyzed and verified from the correlation of experimental and theoretical data. It is found that gamma radiations have changed the bonding structure of

1
2
3 g-C₃N₄ which ultimately reduces the optical bandgap energy. Moreover, the performance
4
5
6
7 of gamma-irradiated g-C₃N₄ is two-fold, compared to that of non-irradiated one; increases
8
9
10 from 3.59 to 5.86 μAcm^{-2} at 1.23 V versus Ag/AgCl in 0.5 M Na₂SO₄ electrolyte solution
11
12
13 (pH 7). Finally, it is observed that the performance of gamma irradiated g-C₃N₄ in g-
14
15
16 C₃N₄@BiVO₄ heterojunction increased from 0.53 mA cm⁻² to 1.38 mA cm⁻², compared to
17
18
19
20 that of the non-irradiated one. In summary, it has been concluded that gamma-irradiated
21
22
23
24 g-C₃N₄ and its heterojunction is potentially be applied in PEC solar water splitting.

55 1. Introduction

56
57
58
59
60

1
2
3
4 Practical solar water splitting requires light absorption, separation and collection of
5
6
7 photogenerated charge carriers, and charge-carrier transport to catalytic sites to
8
9
10 produces gases which must be safely and economically separated and stored¹.

11
12
13
14 Photoelectrolysis of water produces molecular hydrogen and oxygen which is an obvious
15
16
17 and direct way to store solar energy as fuel²⁻⁴. Hydrogen stored its energy in the form of
18
19
20 a chemical bond which directly or indirectly reacts with oxygen to release energy. The
21
22
23 efficient and cost-effective solar water splitting into H₂ and O₂ to produce solar fuel, a
24
25
26 renewable energy carrier, has become a hot research area since 1970s. This research
27
28
29 was spurred by the oil crisis of that period, when the famous paper of Fujishima and
30
31
32 Honda⁵ showed H₂O splitting into H₂ and O₂. This solar water splitting experiment was
33
34
35 achieved by near UV light with the help of photoelectrochemical (PEC) cell.
36
37
38
39
40
41

42 Over the last decade, significant research efforts have been carried out on the efficient
43
44
45 hydrogen production. Numerous semi-conducting materials are employed for the
46
47
48 optimum hydrogen production such as transition metal oxides, perovskites, tuning their
49
50
51 properties via doping, making heterojunctions, and tandem cells. All these
52
53
54
55
56
57
58
59
60

1
2
3 materials/techniques were chosen based on their flexibility, cost effectiveness, and ease
4
5
6
7 of availability. As per our literature review is concerned, the effect of gamma radiation
8
9
10 onto the g-C₃N₄ has become a novel approach in this research area, which is yet be
11
12
13
14 explored.
15
16
17
18
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33

34
35 Exposure of material to ionizing radiation (e.g. X-rays, gamma, beta, alpha and neutron)
36
37
38 may change the physical and chemical properties due to the bond disruption which in turn
39
40
41
42 affects the optical, electrical and structural of the material ⁶. The innovation by employing
43
44
45 the gamma irradiation on g-C₃N₄ semiconductor was chosen due to its high penetration
46
47
48
49 power compared to other ionizing radiation, not contaminate as well as not induce the
50
51
52 material to become radioactive. In addition to that, the alteration to the chemical bonds
53
54
55
56 due to the irradiation may improve the materials performance ⁷. A few research has
57
58
59
60

1
2
3 reported the positive effect of gamma radiation of materials. The effect of gamma
4
5
6
7 radiation on the thin film performance of TeO_2 ⁸ was reported to linearly improve the
8
9
10 current with the increase of gamma dose up to 7 Gy before decreases as gamma dose
11
12
13 approached to 13 Gy. In addition to that, the effects of gamma radiation on the absorption
14
15
16 spectra and optical energy gap of SeO_2 thin film ⁹ was reported to significantly increases
17
18
19 the optical absorption due to changes on the chemical structure of the absorbing species.
20
21
22
23
24 Furthermore, gamma radiations have been developed for the preparation of metal
25
26
27 nanoparticles i.e., Ag ¹⁰, Ni ¹¹, and Zn ¹². The effect of gamma radiation on the formation,
28
29
30 structural, and optical properties of CdS ¹³, PbS ¹⁴, $\text{Fe}_{3-x}\text{O}_4$ ¹⁴, and ZnO ¹⁵ thin films were
31
32
33
34 also reported to improve the bandgap from 3.25 to 3.20 eV, even though deteriorate the
35
36
37 absorption coefficient from 0.62 to 0.73 eV. Therefore, this research aims to investigate
38
39
40 the effect of gamma irradiation on $\text{g-C}_3\text{N}_4$ and $\text{g-C}_3\text{N}_4/\text{BiVO}_4$ in photoelectrochemical
41
42
43
44
45 (PEC) solar water splitting application.
46
47
48
49
50

51
52 The $\text{g-C}_3\text{N}_4$ can be synthesized through nitrogen-rich precursors such as cyanamide,
53
54
55 dicyandiamide, melamine, thiourea, and urea. In this work, urea was chosen as a
56
57
58
59
60

1
2
3 potential precursor due to its availability and low material synthesis cost. Urea was
4
5
6
7 reported as an excellent precursor for the synthesis of sheet-like g-C₃N₄ with high specific
8
9
10 surface area and high porosity ¹⁶⁻²³. However, under visible light radiation, the g-C₃N₄
11
12
13 exhibit weak photocatalytic activity due to its moderate bandgap (2.7 eV) ²⁴. Gamma
14
15
16 irradiation was employed on g-C₃N₄ to improve the PEC performance whereas the BiVO₄
17
18
19 as heterojunction was preferred as a potential material to reinforce its performance in
20
21
22 water splitting application. The formation of the heterojunction is a useful to enhance the
23
24
25 PEC properties, meanwhile matching the band potentials is expected to improve the
26
27
28 photo-conversion efficiency of photogenerated charge carriers. The BiVO₄ is a n-type
29
30
31 semiconductor and has been considered as a promising photoanode ²⁵⁻²⁷ due to its
32
33
34 narrow bandgap (2.4 eV), more active in visible light ²⁸, and can achieve about 9% of
35
36
37 solar-to-chemical conversion. The BiVO₄ has special valence-band position to protoxidize
38
39
40 H₂O, while its conduction band is located close to the H₂ evolution potential ²⁹. The other
41
42
43 advantages of BiVO₄ are non-toxicity, low cost, and environmental friendly material.
44
45
46
47
48
49
50

51
52 Herein, the g-C₃N₄ was irradiated with gamma radiation before deposited onto a substrate
53
54
55 through a spin coating method. Then, in a separate experiment, BiVO₄ was deposited as
56
57
58
59
60

1
2
3 heterojunction through electrodeposition method. To better utilize solar radiation for the
4
5
6
7 improved photocatalytic activity, these two strategies, gamma radiation and
8
9
10 heterojunction were employed. Finally, the density functional theory (DFT) simulations
11
12
13
14 was performed to verify the experimental data. The calculated formation energy
15
16
17 concludes the stability of g-C₃N₄@BiVO₄ interface (heterojunction) and consequences

58
59
60

2.2. Preparation and Synthesis of g-C₃N₄

Fluorine-doped tin oxide glass slides (FTO, TEC 8, ~ 8Ω sq⁻¹ Pilkington) were prepared with a 1.0×2.0 cm² area. The FTO glass was cleaned with acetone, ethanol, and deionized water for 15 minutes successively in an ultrasonic bath and then dried in air. A total 3g of Urea was poured into 50 ml alumina crucible in order to prepare the g-C₃N₄ through a spin coating technique followed by thermal polymerization at the temperature of 520 °C for 30 minutes³⁰. This temperature is essential to thermodynamically driven the reaction which forms g-C₃N₄ from urea, removing oxygen molecules. Finally, a milky yellow powder is formed. A total of 30~40 mg/mL of the powder was dispersed in deionised water and washed for three times to remove any extra organic compound followed by drying in an oven at the temperature of 40 °C for 24 hours. Then, the g-C₃N₄ powder was dispersed in methanol at the ratio of 0.5 mg/L prior irradiated with gamma radiation at the dose of 2, 4, 6, 8 and 10 Gy using a Gamma Cell (model 220 Excel) with Cobalt-60 radioactive source.

1
2
3 For deposition of one-layer g-C₃N₄ thin film, 10 μL of the suspension was spun on a
4
5
6
7 precleaned FTO at 2500 rpm with the acceleration of 500 rpm/s for 10 s. The thin film
8
9
10 was dried for 15 minutes at a temperature of 70 °C to remove alcoholic molecules followed
11
12
13
14 by the annealing at a temperature of 350 °C for 30 minutes.
15
16

17 **2.3. Synthesis of BiVO₄**

18
19
20 The electrodes of BiVO₄ were prepared by an electrodeposition procedure ²⁷. For the
21
22
23 electrodeposition, solutions were prepared by dissolving 10 mM Bi(NO₃)₃ in a solution of
24
25
26
27 35 mM VOSO₄ at < pH 0.5 with HNO₃. Then, 2 M sodium acetate act as a stabilizer was
28
29
30
31 employed to stabilize the solution from the (pH~5.1) to (pH~4.7) with a few amounts of
32
33
34 concentrated nitric acid. The optimum for the electrodeposition BiVO₄ occur at pH 4.7,
35
36
37 where the solution contains Bi (III) and V (IV) ions. Beyond the pH 5.1 value, the solution
38
39
40 becomes precipitate, however, at lower pH (<pH 2), the Bi (III) and V (IV) ions no
41
42
43
44 deposited on the substrate as reported by Seabold and Choi, 2012. ³¹
45
46
47
48

49 A standard three-electrode cell was employed for the electrodeposition, where FTO is
50
51
52 used as working electrode, Ag/AgCl (3 M KCl) as reference, and platinum as counter
53
54
55
56
57
58
59
60

1
2
3 electrode. A potentiostat/galvanostat modulab solatron analytical was used for
4
5
6
7 electrodeposition and all subsequent electrochemical studies. Deposition of amorphous
8
9
10 Bi-V-O films was carried out potentiostatically at 1.9 V vs Ag/AgCl for 5 min at 70 °C (ca.
11
12
13 2 mA/cm²). All thin films were rinsed and then annealed at 500 °C for 1 h in air, with 2 °C
14
15
16 per minute ramping rate. The pure BiVO₄ was obtained by dissolving the V₂O₅ in 1 M
17
18
19 KOH at 20 min stirring. Finally, yellow color was formed on the thin film.
20
21
22
23
24

25 **2.4. Characterization methods**

26
27
28

29 The electrochemical properties of the samples were examined with the help of Autolab
30
31
32 potentiostat/galvanostat PGSTAT 204 at room temperature, using three electrode
33
34
35 configurations with Ag/AgCl (3M NaCl) as reference electrode and 0.5 M Na₂SO₄ (pH 7)
36
37
38 as electrolyte. Platinum was used as counter electrode in a quartz container. The Xenon
39
40
41 lamp with 100 mW/cm² intensity was used as solar light simulator. The electrochemical
42
43
44 circle fitting of Nyquist plots was analysed using Nova Software. The electrochemical
45
46
47 measurements were conducted in dark where incident light intensity of 100Mw cm⁻²,
48
49
50 potential range from -1 to 1.23 V, and scan rate of 20 mVs⁻¹ is employed. PEC
51
52
53
54
55
56
57
58
59
60

1
2
3 measurements were performed on 1.0 cm² area of the working electrode. UV-vis
4
5
6
7 absorption spectrophotometer Perkin Elmer Lambda 950 was used for the
8
9
10 characterization of optical properties. The physical and morphological properties of the
11
12
13 samples were characterized by X-ray Diffraction (XRD), Fourier Transform Infra-Red-
14
15
16 Near Infra-Red (FTIR-NIR) with imaging system (Perkin Elmer Spectrum 400 FT-IR/FT-
17
18
19 NIR & Spotlight 400 Imaging System), Field Emission Scanning Electron Microscopy
20
21
22 (FESEM-EDX) (Supra VP 55) and Atomic Force Microscopy (AFM) (NanosurfeasyScan
23
24
25
26
27
28 2). The X-ray Photoelectron Spectroscopy (XPS) is performed to analyse the chemical
29
30
31 bonding, band structure, and elemental composition of the photoelectrodes, using Al Ka
32
33
34
35 x-ray gun.
36
37
38

39 2.5. First principles study

40
41
42

43 First principles DFT calculations were performed on Quantum-ATK ³² while the results
44
45
46 are visualized on VESTA and Virtual NanoLab Version 2017.1 ³³. BiVO₄ with Hall
47
48
49 symmetry space group of I2/b ³⁴ is used as such. After optimizing the lattice parameters
50
51
52
53 of the bulk unit cell; a supercell (2x2x2) was constructed, from which BiVO₄(001) slab was
54
55
56
57
58
59
60

1
2
3 built. Thickness of the slab was kept as four primitive unit cells of BiVO_4 (10 Å thickness
4
5
6
7 having 96 atoms), to ensure that the centre of the slab can be regarded as the bulk phase.
8

9
10 As discussed in our previous work, the (001) termination possesses low surface energy
11
12
13 and as a result represents the most probable surface termination ³⁵. Stability of these
14
15
16
17 different slabs are confirmed from their positive surface formation energy and electrostatic
18
19
20
21 potential. Single layer $\text{g-C}_3\text{N}_4$ is considered for simulations, the structure of single layer
22
23
24
25 $\text{g-C}_3\text{N}_4$ is illustrated (*vide infra*). Generalized gradient approximation (GGA) with the
26
27
28 Perdew-Burke-Ernzerhof (PBE) exchange-correlation functional and double Zeta
29
30
31 Polarized (DZP) basis set is used for the structural and energy optimization due to its
32
33
34
35 superiority over hybrid pseudopotentials ³⁶. Moreover, linear combination of atomic
36
37
38 orbitals (LCAO) method is used for Bi, V, Ti, C, N, H, and O atoms ³⁷. A 7x7x3 Monkhorst-
39
40
41
42 Pack k-grid and energy cutoff of 1200 eV is used for the BiVO_4 unit cell while a 5x5x1 k-
43
44
45
46 point mesh is used for its slabs. 7x7x7 Monkhorst-Pack k-grid and energy cutoff of 900
47
48
49 eV is used for monolayer $\text{g-C}_3\text{N}_4$, and 5x5x1 k-point mesh with 1200 eV cutoff energy for
50
51
52
53 $\text{g-C}_3\text{N}_4@ \text{BiVO}_4(001)$ heterostructure. The band structure calculations were performed
54
55
56
57 with TB09LDA functional of meta-GGA, which can accurately reproduce the experimental
58
59
60

1
2
3 bandgaps. Recently, Tran and Blaha reported that this accuracy is due to local density
4
5
6 $\rho(r)$ (as in LDA), the gradient of density $\nabla\rho(r)$ (as in GGA), and the kinetic-energy density
7
8
9 $\tau(r)$ ³⁸. The parameter c-equations of the Tran and Blaha XC functions have been installed
10
11
12 to reproduce the experimental bandgap excellently³⁸. Density of states (DOS), partial
13
14
15 density of states (PDOS), band structure and effective masses of photogenerated
16
17
18 electrons and holes are also calculated. The DFT occupied and unoccupied DOS are
19
20
21 considered as the VB and CB edges, respectively; separated by an energy equal to the
22
23
24 known optical bandgap³⁹.
25
26
27
28
29
30

31 32 **3. RESULTS AND DISCUSSION**

33 34 35 **3.1. Structural analysis**

36
37
38 XRD plots of FTO, g-C₃N₄ and gamma radiated g-C₃N₄ along with their corresponding
39
40
41 BiVO₄ heterojunctions are illustrated in Fig. 1. XRD peaks of g-C₃N₄ are in good
42
43
44 agreement with the hexagonal carbon nitride structure with the lattice constants $a= 0.4742$
45
46
47 nm and $c= 6.7205$ nm, which is in according with the literature values of JCPDS 87-1526.
48
49
50
51
52
53 The strong XRD peak at $2\theta = 27.4^\circ$ is originated from the (002) interlayer diffraction of
54
55
56
57
58
59
60

graphitic-like structures, corresponding to an interlayer distance of $d = 0.326 \text{ nm}$ ^{40–42}.

Besides $g\text{-C}_3\text{N}_4$, $2\theta = 13.3^\circ$ ($d = 0.663$), low angle diffraction peak derived from in-planar repeated triazine unit. In case of $g\text{-C}_3\text{N}_4$ powder, two peaks ca. at (100) and (002) planes were observed which correspond to interplanar separation of $g\text{-C}_3\text{N}_4$ sheets and interlayer stacking of the aromatic systems, respectively^{27,42}.

Fig. 1 XRD peaks of (a) FTO (b) $g\text{-C}_3\text{N}_4$ (c) BiVO_4 and (d) gamma radiated $g\text{-C}_3\text{N}_4@ \text{BiVO}_4$.

Thin films of BiVO_4 were successfully deposited through a single step, using electrodeposition method. In case of XRD analysis (Fig. 1c), the characteristic diffraction

1
2
3 peaks are observed at $2\theta = 18.99^\circ, 28.82^\circ, 28.96^\circ, 30.54^\circ, 34.50^\circ, 35.22^\circ, 37.87^\circ, 39.78^\circ,$
4
5
6
7 $42.48^\circ, 46.73^\circ, 47.29^\circ, 50.31^\circ, 53.22^\circ, 58.53^\circ$ and 59.49° . These peaks coincided very
8
9
10 well with the monoclinic clinobisvanite structure of BiVO_4 (JCPD file no. 00-014-0688).

11
12
13
14 The monoclinic clinobisvanite is more prevalent under normal condition and highly
15
16
17 photocatalytically active as well ^{25-27,43}. Due to nearly amorphous structure of $\text{g-C}_3\text{N}_4$, the
18
19
20 peak from $\text{g-C}_3\text{N}_4$ is not clearly visible for gamma radiation in $\text{g-C}_3\text{N}_4@\text{BiVO}_4$ (Fig. 1d).

21
22
23
24 Results and analysis of these finding led us to conclude that there are no impurity
25
26
27
28 diffraction peaks in the XRD patterns of $\text{g-C}_3\text{N}_4@\text{BiVO}_4$, can be indexed as hexagonal
29
30
31 (JCPDS file no. 01-087-1526) for $\text{g-C}_3\text{N}_4$, monoclinic (JCPDS file no. 01-074-4894) for
32
33
34 BiVO_4 . The peak intensity of (121), (040), (051), (042) and (161) support that g-
35
36
37 $\text{C}_3\text{N}_4@\text{BiVO}_4$ has better crystallized structures ^{44,45}. It can be concluded that gamma
38
39
40
41
42 radiation has negligible effect on the crystalline structure of $\text{g-C}_3\text{N}_4@\text{BiVO}_4$ which is due
43
44
45
46 to the close packing of atoms.

47 48 49 **3.2. Chemical composition**

50
51
52 FT-IR has been used to identify organic, polymeric, and inorganic materials in the resulted
53
54
55
56 samples. FT-IR spectra of the $\text{g-C}_3\text{N}_4$ and gamma irradiated Gy (2,4,6,8,10) $\text{g-C}_3\text{N}_4$ are

1
2
3 shown in Fig. 2. Five peaks can be clearly observed in the FT-IR spectra where the strong
4
5
6
7 peak at ca. 810 cm^{-1} corresponds to the out of plane ring bending of the triazine unit ^{40,46}.
8
9
10 The peak ca. at 1630 cm^{-1} corresponds to the C-N heterocycle, stretching vibrations
11
12
13 modes, whereas the peaks ca. at 1450 and 1250 cm^{-1} can be assigned to aromatic C-N
14
15
16 stretching vibration modes ^{47,48}. The broad bands between 3000 cm^{-1} and 3600 cm^{-1} are
17
18
19 attributed to the secondary and primary amines, respectively ^{40,49}. Gamma radiation
20
21
22 modify and change the chemical structures of pure g-C₃N₄ for the peak ca. at 810 cm^{-1} ,
23
24
25 denotes triazine unit and became sharper at 8Gy g-C₃N₄. Meanwhile, 1250 cm^{-1} peak
26
27
28 represent the aromatic C-N and became strong light absorber due to ionizing of gamma
29
30
31 radiation. The sharp peak ca. at 1250 cm^{-1} is an indication of good crystallinity of g-C₃N₄
32
33
34 due to gamma radiation ⁴⁶. Obviously, the characteristic peaks of 3200 cm^{-1} became
35
36
37 stretching upon gamma irradiation. According to Knoll ⁵⁰, when radiation interacts with
38
39
40 semiconductor, the energy deposition always leads to the creation of equal number of
41
42
43 holes and electrons on material. Thus, the energy from gamma radiation may interrupt
44
45
46 the C-N bonding and electrons become stronger and easily migrate in atom.
47
48

50
51
52
53
54
55
56
57
58
59
60

Fig. 2 FT-IR spectra of g-C₃N₄ and irradiated g-C₃N₄.

3.3. Electronic interaction analysis

XPS analysis was carried out to get additional insight into the chemical composition of g-C₃N₄ and radiated-g-C₃N₄ on thin films, as shown in Fig. 3. High resolution spectra of C 1s ca. at 284.60 and 288.0 eV are shown in Fig. 3a. The peak for 284.6 eV can be attributed to the adventitious carbon, adsorbed on the surface and the peak of 288.0 eV is related to sp² hybridizes carbon in N containing aromatic rings (N-C=N) of g-C₃N₄⁵¹. The high resolution XPS scan of N1s for g-C₃N₄ and radiated g-C₃N₄ are given in Fig. 3b. There are four main peaks ca. at 398.4, 399.4, 400.7, and 403.5 eV. The main peaks ca.

1
2
3
4 at 398.4 and 399.4 eV are assigned to the sp^2 hybridized aromatic of N to carbon atoms
5
6
7 in triazine unit (C-N=C) and the tertiary N bonded to carbon atoms (N-(C)₃), respectively.
8

9
10 The peak ca. at 400.7 eV belongs to the amino group (C-N-H), from the defect of g-C₃N₄
11
12
13
14 ^{27,42,52}. Additionally, the peak for 403.5 eV shows π -excitation, which comes from charging
15
16
17 effect or positive charge localization in the heterocycles ^{51,53}. Both XPS spectra of C1s
18
19
20 and N1s reveal that an electronic interaction occurs due to gamma radiation on g-C₃N₄,
21
22
23
24 indicating that gamma radiation has produced a nice contact interfaces in the samples.
25
26
27

28 When photon interacts, it might be absorbed and disappear or it might be scattered,
29
30
31
32 changing its direction of travel, with or without loss of energy ⁵⁴. The gamma radiation
33
34
35 causes the bonding between carbon and nitrogen to break and modified the structure
36
37
38
39 (see Fig. 3). This is due the ionization between the metallic bond. Ionization will enhance
40
41
42 the kinetic energy of the electrons or excites the electrons to a higher energy level.
43
44
45

46 However, ionization can also make a displacement in the material ⁵⁵. This is clearly seen
47
48
49 in XPS images as the amplitude intensity of XPS for radiated g-C₃N₄ is less than that of
50
51
52
53 pure g-C₃N₄. The breaking of carbon and nitrogen bond induces the formation of free-
54
55
56
57
58
59
60

1
2
3 carriers such as carbon and nitrogen. The free carriers then react with intrinsic oxygen in
4
5
6 carbon nitride structure to form extra oxygen bonding that is clearly illustrated in the FTIR
7
8
9 spectra (see Fig. 2). The reason behind this is, the free carbon atoms are more willing to
10
11
12 make bonding with more electronegative oxygen compared to that of less electronegative
13
14
15
16
17 nitrogen.

Fig. 3 XPS survey scans of a) C 1s and b) N 1s for g-C₃N₄ and radiated g-C₃N₄.

Fig. 4 X-ray photoelectron spectra (XPS) survey spectrum for BiVO_4 . High resolution X-ray photoelectron spectra of as deposited Bi-V-O film showing the b) Bi 4f, c) V 2p and d) O1s.

In (Fig. 4), the full survey spectra of BiVO_4 and their elements such as Bi, V, O are displayed from the XPS spectrum. It is clearly seen that $\text{g-C}_3\text{N}_4/\text{BiVO}_4$ thin film, does not influences the peak intensity for C1s and N1s due to the overlap of $\text{g-C}_3\text{N}_4$ and BiVO_4 . The thickness of BiVO_4 around 365 nm will cover all the $\text{g-C}_3\text{N}_4$ surface and consequences, overlapping with elements of Bi, V and O. The high resolution XPS

1
2
3 spectra of deposited Bi-V-O film show the Bi 4f, V 2p peaks and O 1s. The position of the
4
5
6
7 Bi and V peaks matches very well with those of Bi³⁺ and V⁵⁺ ions in oxides. The peaks of
8
9
10 BiVO₄ are 4f 7/2 (159.0 eV), 4f 5/2 (164.45 eV), 2p 1/2 (516.30 eV), 2p 3/2 (525.0 eV) and
11
12
13
14 O 1s (530.49 eV)^{27,31}.
15
16
17

18 3.4 Optical properties and Band Gap Energy

19
20
21

22 The optical absorption spectrum is one of the most important tools for developing the
23
24
25 energy band diagram. Fig. 5 shows an absorption spectrum for g-C₃N₄ and radiated g-
26
27
28 C₃N₄ in liquid phase. The absorption spectrum of g-C₃N₄ and gamma radiated g-C₃N₄ in
29
30
31 the wavelength range of 200 -700 nm are show in (Fig. 5a). The absorption of amino peak
32
33
34 is located at 230 nm and the strong absorption band ca. at 320 nm shows carbon nitride
35
36
37 bond in conjugation^{56,57}. All these peaks indicate that g-C₃N₄ is sussesfully synthesized
38
39
40 from urea. However, ionizing from gamma radiation modify and change the peak intensity
41
42
43
44 of g-C₃N₄. Compared with pure g-C₃N₄ sample, radiated g-C₃N₄ samples show an
45
46
47
48 intensive absorption ca. at 400 nm in the visible light region. This broad absorption ban
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 peak may arise due to the ionizing effect on bonding $g\text{-C}_3\text{N}_4$. Particularly, radiated $g\text{-C}_3\text{N}_4$,

5
6
7 8 Gy presents the most intensive broad absorption in the visible light region.
8
9

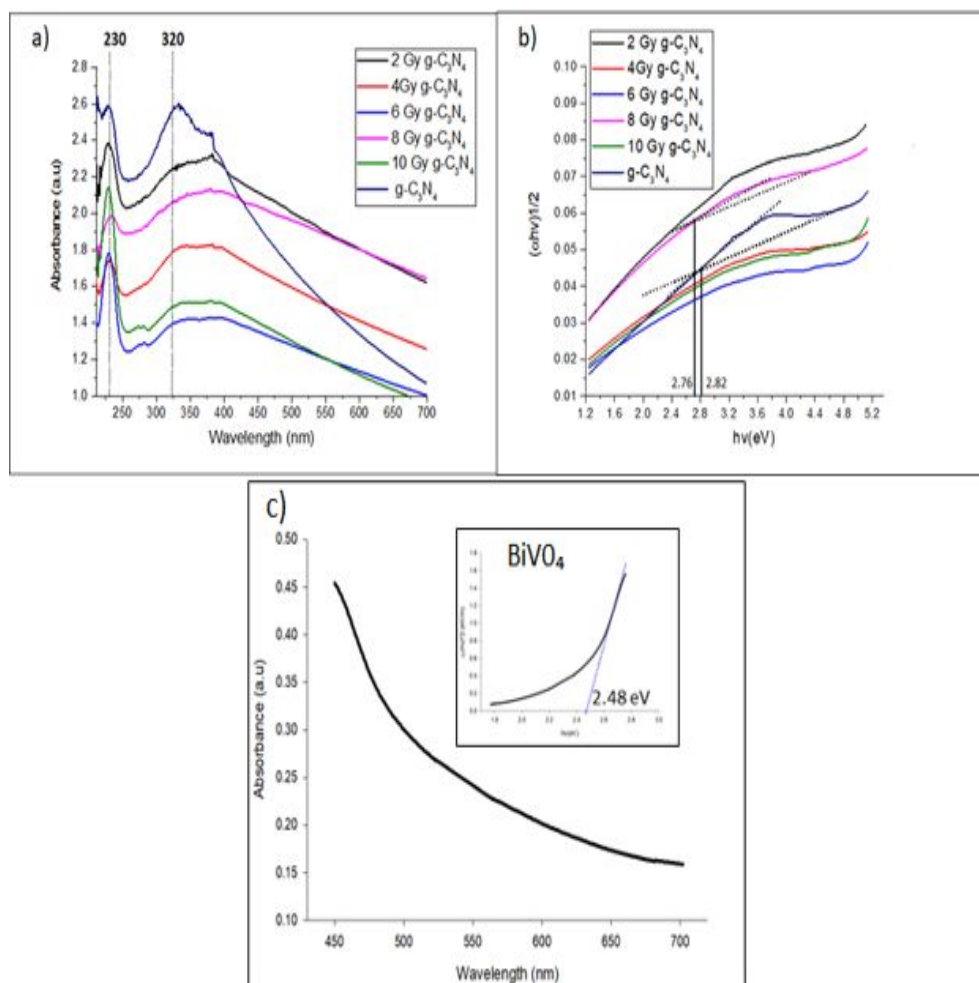

Fig. 5 a) UV-Vis absorbance spectra of $g\text{-C}_3\text{N}_4$ and radiated $g\text{-C}_3\text{N}_4$ b) estimation of bandgap energy by a Tauc Plot and c) BiVO_4 absorption UV-Vis (insert: estimation of band gap).

1
2
3 Obviously, the value of optical band gap decreases from 2.82 to 2.76 eV when g-C₃N₄
4
5
6
7 was treated by gamma radiation (see Fig. 5b). The reported band gap energies of g-C₃N₄
8
9
10 from urea in the range 2.69 to 2.88 eV depend on the different reaction parameter
11
12
13 (annealing temperature, duration and atmosphere effect) ⁵⁸ Dong et al.⁴⁸ reported 2.72
14
15
16 eV band gap for g-C₃N₄, synthesized from urea by the pyrolysis technique ⁴⁸. Meanwhile,
17
18
19 Su et al ⁵⁹ reported 2.58 eV (band gap) for g-C₃N₄, synthesized by hydrothermal process.
20
21
22
23
24 Due to the ionizing from gamma radiation, the band gap for g-C₃N₄ decrease to 2.76 eV.
25
26
27
28 Furthermore, Arshak and Kerostynska ⁶⁰ reported the decrease in the optical band gap,
29
30
31 from 3.75 eV for as deposited TeO₂ thin films to 3.45 eV for the gamma radiation on TeO₂
32
33
34 thin films for a dose of 36Gy. Ahmad et al. ⁶¹ also reported that gamma radiation shifted
35
36
37 the Fermi level and the reduction in optical band gap from 2.14 to 2.06 eV, 2.19 to 1.99
38
39
40 eV and 2.25 to 2.09 eV of thin films of Cd₅Se_{95-x}Zn_x (x = 0,2,4) after radiated on 75 kGy
41
42
43
44 of gamma radiation. Meanwhile, Al-Hamdani et al. ¹⁵ found that, the gamma radiation also
45
46
47 effect the performance of ZnO thin films and the band gap decrease from 3.25 to 3.2 eV.
48
49
50
51
52 This decrease in optical band gap is basically due to the increase in the energy width of
53
54
55 band tails of localized state, similar observations have been reported by other researcher
56
57
58
59
60

1
2
3 as well ^{29,62,63}. Meanwhile, (Fig. 5c) shows a photoanode absorption and the direct band
4
5
6
7 gap transition of BiVO₄ thin films. The absorption was determined from the plots of $(\alpha h\nu)^2$
8
9
10 vs $(h\nu)$ and the estimated bandgap energy is 2.48 eV ^{27,44,45}.

14 3.5 Morphology

15
16
17
18 The surface morphology of g-C₃N₄, and radiated g-C₃N₄ along with their corresponding
19
20
21
22 BiVO₄ heterojunctions are determined by FESEM-EDX and mapping with 200 nm
23
24
25 resolutions. These films consisted of mesoporous g-C₃N₄ and look like a “seaweed”
26
27
28
29 architecture picture structure as shown in (Fig. 6). Both FESEM images show that gamma
30
31
32
33 radiation does not influence the morphology of the g-C₃N₄.

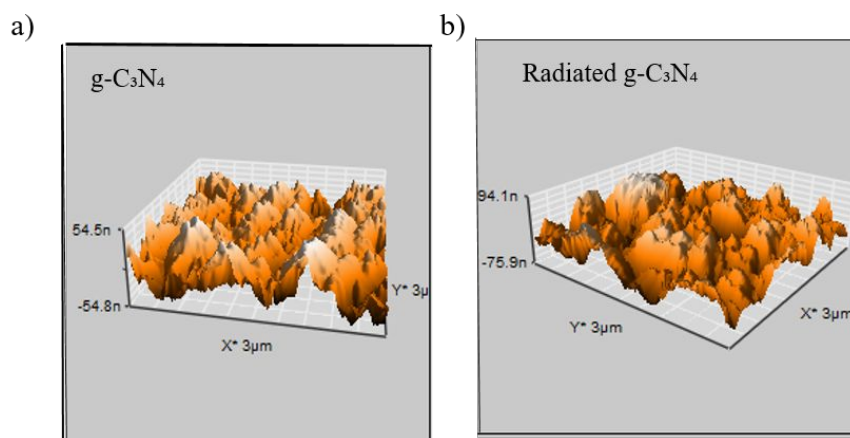

Fig. 6 FESEM-EDX images of (a) g-C₃N₄ (b) radiated g-C₃N₄ (8Gy), (c) (d) EDX and mapping of g-C₃N₄.

g-C₃N₄ is distributed on the surface of FTO by spin coating method. Several processing parameters are involved in the spinning process such as solution viscosity, solution concentration, spin time, and spin speed⁶⁴. This technique is necessary which form a uniform layer to prevent a pinhole and large surface area for absorbing more light^{44,65,66}. The existences of the elements of C and N in the samples was supported by EDX analysis as shown in (Fig. 6c). It can be observed no other impurity peak was detecting, except

1
2
3 the peak of Sn (probably was attributed to the FTO). The mapping results are supported
4
5
6
7 in (Fig. 6d) to ensure that the g-C₃N₄ is uniformly distributed on thin films. The blue and
8
9
10 red color are good indication for the elements of N and C, respectively.

11
12
13
14 Surface roughness of g-C₃N₄ and gamma radiated g-C₃N₄ were compared and presented
15
16
17 in (Fig. 7(a-b) and table 1 along with their 3D view. Although, the AFM images show less
18
19
20 noticeable changes in thin films topology whereas the gamma radiated g-C₃N₄ has
21
22
23 recorded the highest surface roughness compared to pure g-C₃N₄. Hence, this indicate
24
25
26 that gamma radiation on the g-C₃N₄ already transform the topology of the films. Generally,
27
28
29 high surface roughness and small grain size can significantly affect the PEC performance,
30
31
32 as more sites are exposed in the photocatalytic reaction ^{27,66,67}.

54
55 **Fig. 7** AFM images for a) g-C₃N₄ and b) gamma radiated g-C₃N₄.

Table 1 Surface roughness of g-C₃N₄ and gamma radiated g-C₃N₄ determined by AFM.

Sample	Surface roughness (nm)
g-C ₃ N ₄	19.72
Radiated g-C ₃ N ₄	28.24

Under visible light irradiation, BiVO₄ has a direct bandgap of approximately 2.4 eV, allowing efficient absorption of photons. Therefore, the formation of a heterojunction of g-C₃N₄ with BiVO₄ is a good strategy to improve the photo-conversion efficiency of photogenerated charge carriers. The ability of BiVO₄ to absorb visible light would achieve about 9% of solar to chemical conversion. The development of heterojunction with BiVO₄ suppresses its charge recombination by improving the charge transport properties^{27,52,66}. Furthermore, various deposition methods have been employed to synthesize BiVO₄ such as chemical bath deposition (CBD), Aerosol - assisted chemical vapor deposition (AACVD), electrodeposition and hydrothermal. Herein, the heterojunction is established

1
2
3 by electrodeposition method, an useful approaches to enhances the PEC properties.

4
5
6
7 Electrodeposition has the distinctive advantages of being simple, low cost, and easy

8
9
10 scalable while enabling deposition of the material of interest on the conductive substrate

11
12
13 and not on the chamber wall.

34 **Fig. 8** FESEM-EDX of a) BiVO₄ and b) gamma radiation on g-C₃N₄@BiVO₄.

35
36
37 The FESEM-EDX surface morphology of the BiVO₄ and gamma radiated g-C₃N₄@BiVO₄

38 thin film are shown in (Fig. 8a) and b). It is clearly seen that the BiVO₄ morphology

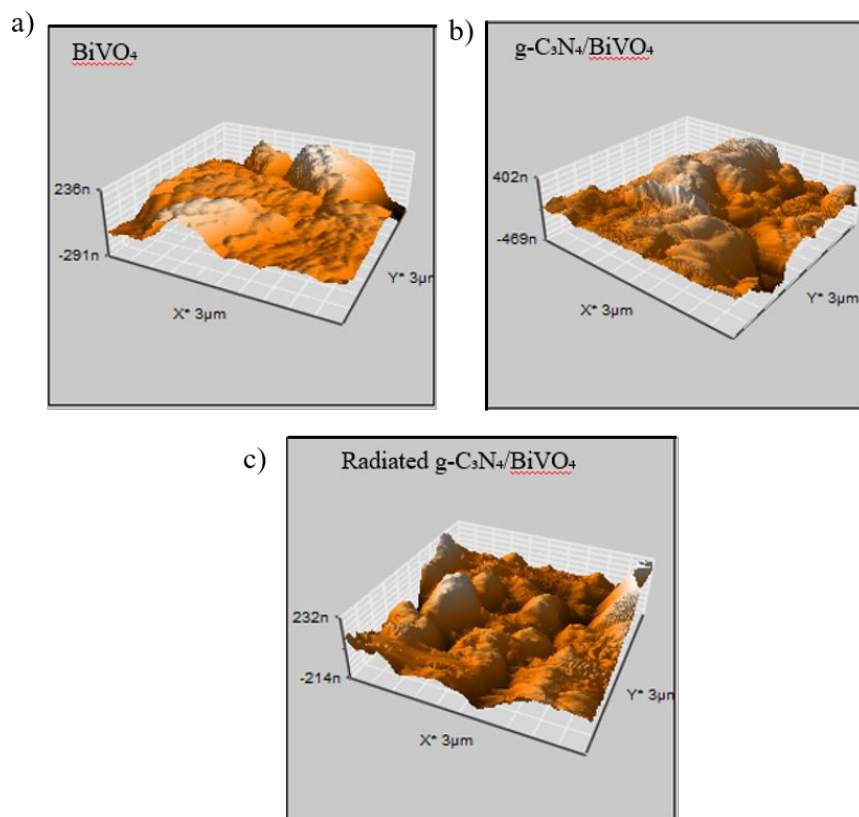

39 comprised of a “flower” like architecture image. Furthermore, for the gamma radiated g-

40
41 C₃N₄@BiVO₄, some of the particles seemed to agglomerate and form high rough surface.

42
43
44
45
46
47
48 This result is also in consistent with results obtained from AFM analysis, shown in (Fig.9).

49
50
51
52
53
54
55 Interestingly, the agglomerated morphology of BiVO₄ would enlarge the active sites at the

1
2
3 interface between photoanode and the electrolyte, which will enhance the light
4
5
6
7 absorption. Therefore, more electrons and holes would participate in the reaction at the
8
9
10 interface which ultimately improve the photocatalytic activities. However, the images for
11
12
13 unirradiated $\text{g-C}_3\text{N}_4$ with heterojunction BiVO_4 are not display as gamma radiation does
14
15
16
17 not influence the structure of $\text{g-C}_3\text{N}_4$, see the discussion of (Fig.6). The existence of Bi,
18
19
20
21 V, O, N, and C elements were supported by EDX analysis.

1

Fig. 10 FESEM cross sectional images of BiVO₄ and gamma radiated g-C₃N₄@BiVO₄

3.6 PEC performance

As discussed above, g-C₃N₄ is a great potential material for photocatalytic reaction and has received an intensive attention due to its unique electronic property such as visible light response, good reduction ability, easy synthesis and have a high stability. So, gamma radiation on g-C₃N₄ and its heterojunction with BiVO₄ have been used as useful approaches to enhances the PEC in water splitting. In this research, the effect of gamma

radiation on g-C₃N₄ at the dose of 2, 4, 6, 8, and 10 Gy was discussed and compared with the non-irradiated samples.

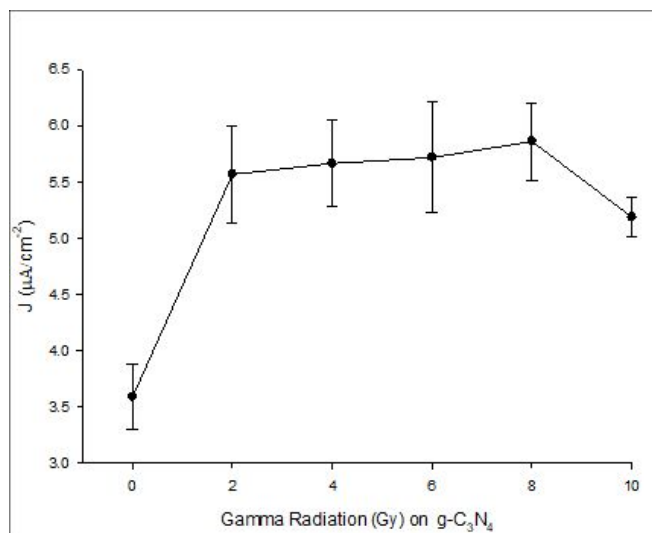

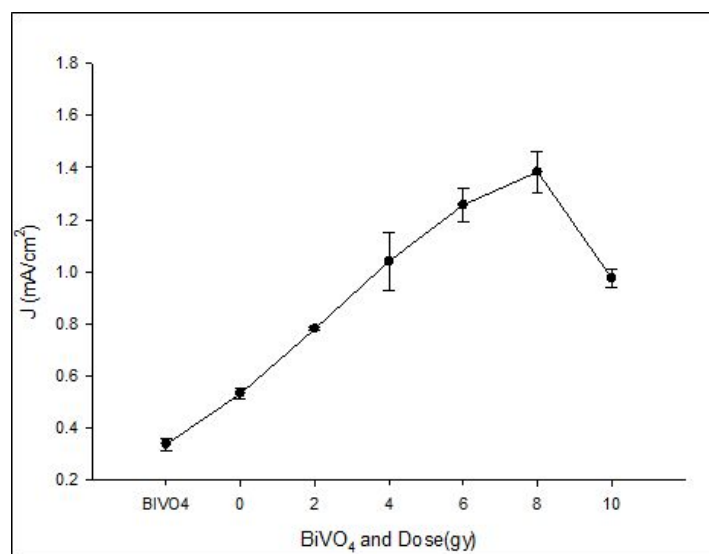

Fig. 11 J-V versus gamma radiation on g-C₃N₄. Error bars display one standard deviation from the mean of four replicate.

Comparative analysis the data from (Fig. 11) led us to conclude that the different doses resulted in the different performance of g-C₃N₄ semiconductor. Clearly, a lower dose of gamma radiation was found to increase the current density quite linearly from 2 Gy to 8 Gy, whereas the current density decreases at 10 Gy. Gamma radiation on solid material produces microstructural change which in turn changes the optical and other properties of the material⁶⁸. Furthermore, there are two process occur when gamma radiation

1
2
3
4 interacts with the material, defect creation and defect annihilation. This can be seen in
5
6
7 (Fig. 2) as the chemical structure of $g\text{-C}_3\text{N}_4$ was altered by gamma radiation which led to
8
9
10 the improvement of the photocurrent density from $3.59 \mu\text{Acm}^{-2}$ $g\text{-C}_3\text{N}_4$, to $5.86 \mu\text{Acm}^{-2}$ for
11
12
13 unirradiated and irradiated $g\text{-C}_3\text{N}_4$, respectively (Fig. 11). The changes properties of the
14
15
16 material will depend on these two processes or on the other hand it depends on the
17
18
19 irradiation dose. This is due to higher doses of gamma radiation, the number of defects
20
21
22 created becomes more than the number of defects annihilated, the reverse is true at lower
23
24
25 doses of gamma radiation. Gamma irradiation on materials may cause re-crystallization
26
27
28 or amorphization depends on the nature of the material and irradiation dose of gamma
29
30
31 radiation. From above discussion, the probability of recrystallization is more at lower
32
33
34 doses of gamma radiation whereas the amorphization of the material is prominent at
35
36
37 higher doses of gamma radiation.

38
39
40
41
42
43
44
45 However, $g\text{-C}_3\text{N}_4$ exhibit weak photocatalytic activity due to its wide bandgap energy (2.71
46
47
48 eV) ^{27,42,52} , which can be activated by visible light irradiation only. Herein, the idea of
49
50
51 heterojunction with BiVO_4 as useful approach to improve the PEC water splitting. Fig. 12
52
53
54 shows a photocurrent density of gamma radiation of $g\text{-C}_3\text{N}_4$ heterojunction BiVO_4 , and
55
56
57

1
2
3 non- irradiated g-C₃N₄ heterojunction with BiVO₄. For the BiVO₄, the current density is
4
5
6
7 0.34 mA/cm² at 1.23 V as reported by Seabold and Choi³¹. The current density increase
8
9
10 linearly as shows in (Fig. 12), however it drops linearly at high dose such as 10 Gy of
11
12
13 gamma radiation. The effects of ionizing radiation on metal oxide thin films depend on the
14
15
16 radiation dose and parameters of the films, including the film thickness. Probably, due to
17
18
19
20
21 the ionizing radiation from free radical with dose of 10 Gy, the physical properties such
22
23
24
25 as optical and electrical alter the performance of the g-C₃N₄@BiVO₄ heterojunction.

1
2
3
4 In this study, the effect of gamma radiation on g-C₃N₄ semiconductor material (2, 4, 6, 8
5
6
7 and 10 Gy) was discussed and compared with the non-irradiated samples. The PEC
8
9
10 performances were recorded by using 3 electrode configurations, such as g-C₃N₄ as
11
12
13 working electrode, platinum as a counter electrode, and Ag/AgCl as references electrode;
14
15
16 under 1.5 AM solar simulator with a 0.5 M Na₂SO₄ electrolyte. Photocurrent density
17
18
19 versus potential (Voltage versus Ag/AgCl) shows a good photocatalytic response under
20
21
22 both dark and visible light irradiations. In (Fig. 13a), a good photocatalytic response
23
24
25 between g-C₃N₄ and gamma radiation g-C₃N₄ can be seen. Irradiated g-C₃N₄ has two-
26
27
28 times better performance which increase from 3.59 to 5.86 μAcm^{-2} at 1.23V versus
29
30
31 Ag/AgCl in 0.5 Na₂SO₄ electrolyte solution (pH 7). Ionizing radiation produces a free
32
33
34 radical to induces chemical reaction, happen on semiconductor g-C₃N₄. The small
35
36
37 difference between treated g-C₃N₄ and non-irradiated g-C₃N₄ shows that gamma
38
39
40 radiation can change the electrical properties of the g-C₃N₄ and improve in PEC water
41
42
43
44
45
46
47
48
49 splitting.

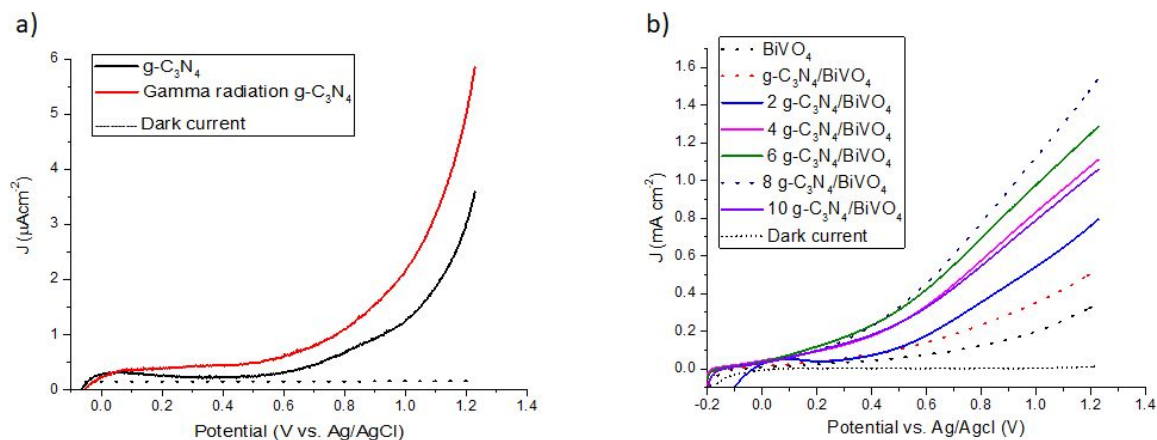

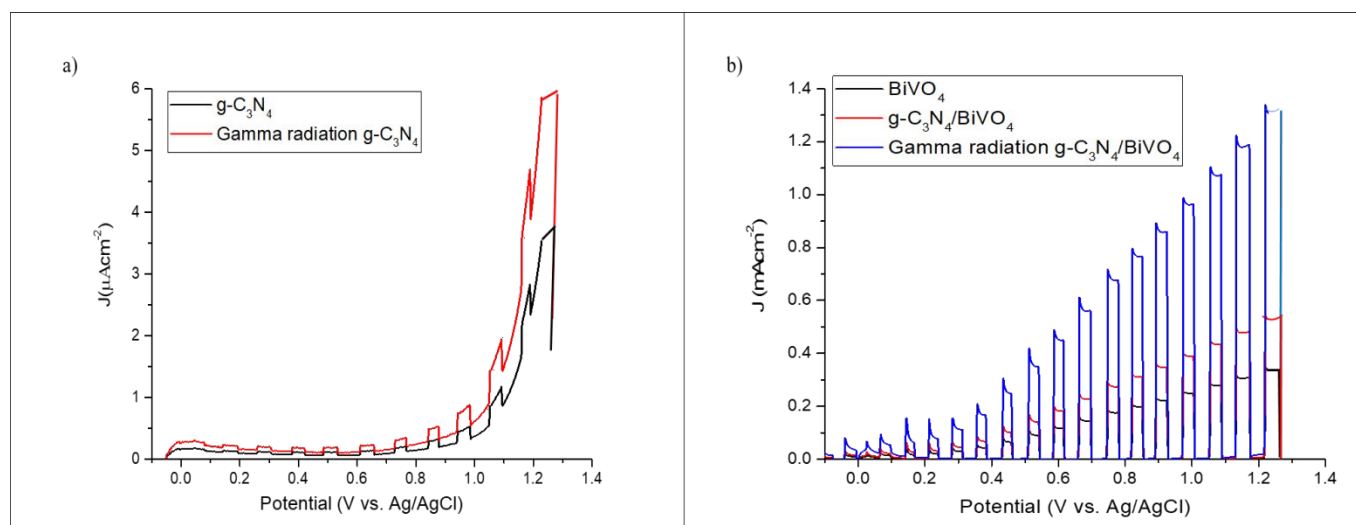

Fig.13 J-V curves for a) comparison of g-C₃N₄ and gamma radiated g-C₃N₄ (2, 4, 6, 8 and 10 Gy) b) J-V curve for BiVO₄, g-C₃N₄@BiVO₄ and gamma radiation g-C₃N₄@BiVO₄ in the dark and light illumination in 0.5 M Na₂SO₄ (pH7) electrolyte.

The photocurrent density versus potential (voltage versus Ag/AgCl) for BiVO₄ as a control, g-C₃N₄@BiVO₄ and gamma irradiated g-C₃N@BiVO₄ were investigated, which are shown in (Fig. 13b). BiVO₄ is an *n*-type semiconductor and serve as a photoanode which generate anodic photocurrent through the consumption of photoinduced holes for water oxidation at the semiconductor/electrolyte interface^{25,27,31}. Under 100 mWcm⁻² light intensity, the photocurrent density recorded was 0.33 mAcm⁻² at 1.23 V versus Ag/AgCl.

1
2
3
4 Meanwhile, the photocurrent density increases almost two-times in case of g-
5
6
7 $C_3N_4@BiVO_4$ heterojunction. In summary, studies have found that gamma radiation
8
9
10 enhances the PEC water splitting performance of g- C_3N_4 . Moreover, the photocurrent of
11
12
13
14 gamma irradiated g- $C_3N_4@BiVO_4$ heterojunction increased from 0.78 to 1.38 $mAcm^{-2}$ by
15
16
17 2 Gy until 8 Gy. However, the photocurrent density decreased to 0.97 $mAcm^{-2}$ when 10
18
19
20 Gy of gamma radiation is used. Due to high dose of gamma radiation, ionizing radiation
21
22
23
24 produces changes in the physical properties (such as optical, electrical and structural) of
25
26
27
28 the material ⁸. In this case, gamma radiation changes the chemical bonding as discussed
29
30
31 in (Fig. 2-3). Under dark current situation, the photocurrent was almost negligible and
32
33
34
35 showed high response after being illuminated. So, it can be concluded that light has been
36
37
38
39 absorbed by FTO and results less photocurrent which consequences fewer pinholes in
40
41
42
43 the photoanode and can ultimately reduce its photocurrent density.

44
45
46 Furthermore, photocurrent density of treated g- C_3N_4 and non-treated g- C_3N_4 with spin
47
48
49 coating technique, responsive to the light and dark are shown in (Fig.14a). Analysis of
50
51
52
53 this figure consequences that current occurs in light at - 0.1 V which indicates the

1
2
3 recombination process between the semiconductor and electrolyte. So, spin coating
4
5
6
7 method is important to ensure the $g\text{-C}_3\text{N}_4$ was deposited uniformly on thin film to prevent
8
9
10 the pinholes. High surface area of $g\text{-C}_3\text{N}_4$ results in higher light absorption which will
11
12
13
14 further increase the current density.

37 **Fig. 14** a) Photoresponse of $g\text{-C}_3\text{N}_4$ and gamma treated $g\text{-C}_3\text{N}_4$ b) photoresponse of
38
39
40 BiVO_4 , $g\text{-C}_3\text{N}_4@\text{BiVO}_4$ and gamma irradiated (8Gy) on $g\text{-C}_3\text{N}_4@\text{BiVO}_4$ under light and
41
42 dark in 0.5 M Na_2SO_4 .

43
44
45
46
47
48 The photoresponse pattern of thin film BiVO_4 , $g\text{-C}_3\text{N}_4@\text{BiVO}_4$ and gamma radiated $g\text{-C}_3\text{N}_4@\text{BiVO}_4$,
49
50 under the light and dark at 100 Mw cm^{-2} light intensity is shown in (Fig.

51
52
53
54
55
56
57
58
59
60
14b) Comparative analysis of these pattern show that all material represents a

1
2
3 photoactive thin film. It is known that a short deposition time results thinner films, whereas
4
5
6
7 a longer time corresponds to thicker films, therefore that is why 5 minutes of time
8
9
10 deposition has been selected. As the films thickness increase, the sample produces lower
11
12
13 photocurrent density. This might be due to the greater distance travelled by the charge
14
15
16 carriers, thereby increasing the recombination rate of electron-hole pairs. In case of
17
18
19 thinnest films, the short distance travelled by charge carriers compared to its diffusion
20
21
22 length. Therefore, the charge carriers do not have enough time to diffuse to electron-hole
23
24
25 pairs. Lastly, the as-fabricated heterojunction demonstrated a negligible photocurrent
26
27
28 reduction under 395 nm cut-off filter, affirming the high contribution of visible light in photo-
29
30
31 generation and transportation of exciton (Fig. S1).

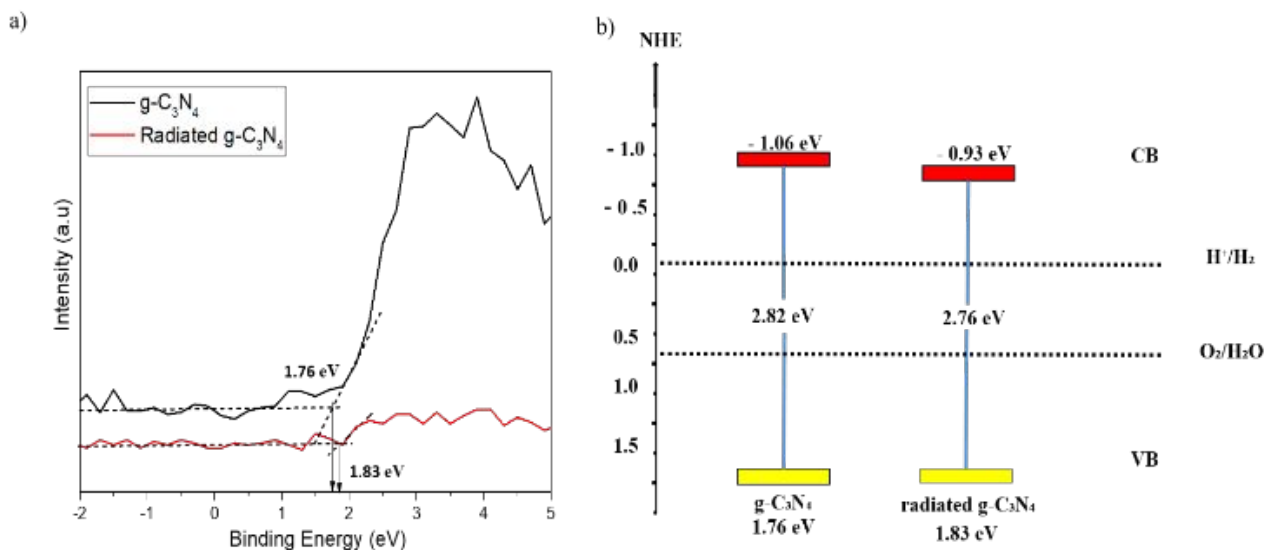

Fig. 15 a) Valence band XPS spectra of $g\text{-C}_3\text{N}_4$ and radiated $g\text{-C}_3\text{N}_4$. b) Schematic

illustration of the band structures of $g\text{-C}_3\text{N}_4$ and radiated $g\text{-C}_3\text{N}_4$.

The efficiency of separation and transfer of photoinduced electron-hole was known as the key factor to improve the photocatalytic activity^{42,69}. The potential positions of the conduction band (CB) and valence band (VB) of $g\text{-C}_3\text{N}_4$ may affect the efficiency of separation and transfer of photoinduced electron-hole. A comparison of radiated $g\text{-C}_3\text{N}_4$ and unirradiated $g\text{-C}_3\text{N}_4$ was examined by the valence band X-ray photoelectron spectroscopy (VB XPS). The values of E_{VB} for $g\text{-C}_3\text{N}_4$ and radiated $g\text{-C}_3\text{N}_4$ were revealed to be about 1.76 eV and 1.83 eV. Band gap which is referred to E_g , was estimated to be

1
2
3 about 2.82 eV and 2.76 eV from previously obtained Tauc-plots, respectively. Using the
4
5
6
7 formula, $E_{CB}=E_{VB}-E_g$, the values of ECB was calculated to be about -1.06 eV and -0.93
8
9
10 eV. In short, (Fig. 15b) shows that the conduction band and valence band potentials of g-
11
12
13 C_3N_4 respectively became less negative and more positive upon gamma radiation. As it
14
15
16
17 was demonstrated in (Fig. 3), both N1s and C1s orbitals underwent hybridization upon
18
19
20 gamma irradiation. Since the VB of g- C_3N_4 is principally comprised of N1s orbitals while
21
22
23 its CB mainly consists of C1s orbitals, both valence and conduction band energies of g-
24
25
26
27 C_3N_4 are modified upon gamma radiation ^{27,52}.

31 **3.9 First Principles study of g- $C_3N_4@BiVO_4$ Heterojunction**

32
33
34 The experimental data of g- $C_3N_4@BiVO_4$ Heterojunction is reproduced from DFT
35
36
37 simulations. DFT simulations are carried out for individual $BiVO_4(001)$, g- C_3N_4 , and g-
38
39
40 $C_3N_4@BiVO_4(001)$ heterostructure, relaxed structures are shown in (Fig. 16). Our
41
42
43 theoretical data predict that g- $C_3N_4@BiVO_4$ has negligible mismatch (0.02 %), which
44
45
46
47 finally consequences its strong overapplying. Before making heterojunction, the surface
48
49
50 stability of $BiVO_4(001)$ is confirmed from its positive surface formation energy of 1.95 J/m².
51
52
53
54
55
56 So, due to it stability, $BiVO_4(001)$ slab was chosen to construct g- $C_3N_4@BiVO_4(001)$
57
58
59
60

1
2
3 heterostructure. The construction of $g\text{-C}_3\text{N}_4@\text{BiVO}_4(001)$ heterostructure by placing a
4
5
6
7 single layer of $g\text{-C}_3\text{N}_4$ on the top of $\text{BiVO}_4(001)$ slab, see (Fig. 16c). Hereafter, the $g\text{-}$
8
9
10 $\text{C}_3\text{N}_4@\text{BiVO}_4(001)$ will be denoted as $g\text{-C}_3\text{N}_4@\text{BiVO}_4$.

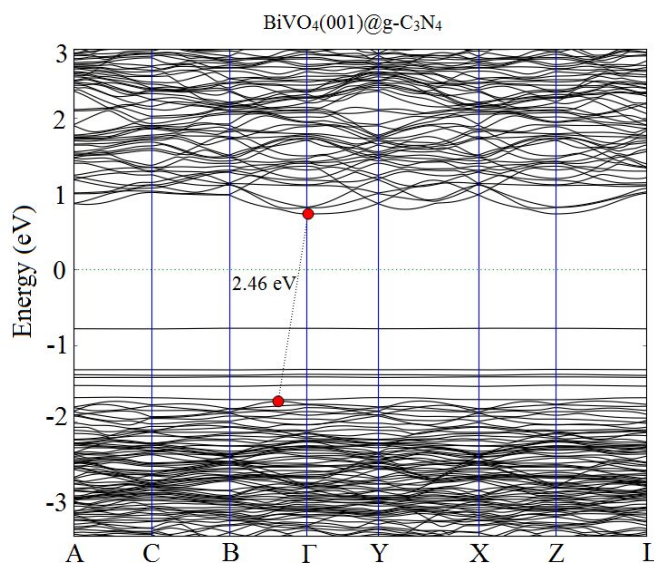

32 **Fig. 16** Optimized crystal structures of (a) $\text{BiVO}_4(001)$, (b) $g\text{C}_3\text{N}_4$ and (c)
33
34
35 $g\text{C}_3\text{N}_4@\text{BiVO}_4(001)$ heterojunction.²⁷

36
37
38
39 From the relaxed crystal structure of heterojunction, it is found that $g\text{-C}_3\text{N}_4$ form a non-
40
41
42 covalent bondings with the surface of BiVO_4 through Bi-N , O-C , and O-N ; reveals
43
44
45 strong van der Waal interaction between them. Moreover, the calculated adsorption
46
47
48 energy of $g\text{-C}_3\text{N}_4$ nanosheet over the $\text{BiVO}_4(001)$ is -0.68 eV which also confirm the
49
50
51
52
53
54
55
56
57
58
59
60

thermodynamic stability of g-C₃N₄@BiVO₄ heterojunction. The adsorption or interface adhesion formation energy was calculated with the help of eq 2.

$$\Delta E_{\text{ad}} = E_{\text{g-C}_3\text{N}_4\text{@BiVO}_4} - (E_{\text{g-C}_3\text{N}_4} + E_{\text{BiVO}_4(001)}) \quad (2)$$

where $E_{\text{g-C}_3\text{N}_4\text{@BiVO}_4}$, $E_{\text{g-C}_3\text{N}_4}$, and $E_{\text{BiVO}_4(001)}$ represent the total energy of the relaxed g-C₃N₄/BiVO₄ heterojunction, monolayer g-C₃N₄, and BiVO₄(001) slab, respectively. The electronic properties of g-C₃N₄@BiVO₄ heterostructure such as band structure and PDOS are simulated, to double check the experimental data. The simulated band structure of g-C₃N₄@BiVO₄ is shown in (Fig. 17), where an indirect bandgap of 2.46 eV is consistent with our experimentally observed band gap.

1
2
3
4 **Fig. 17** Band structure of $gC_3N_4@BiVO_4$ heterojunction.²⁷
5
6
7

8 The VBM of $g-C_3N_4@BiVO_4$ heterostructure is located between B and Γ points, whereas
9
10 the CBM is at Γ point (see Fig. 17). Upon interaction of $g-C_3N_4$ with $BiVO_4(001)$, flat bands
11
12 are produced in the VB of the resulted heterojunction, responsible for the VB of
13
14 heterojunction which consequently lead to holes trapping. The enhanced overall
15
16 photocatalytic activity or high charge carrier mobility can be related to these flat bands.
17
18 The contribution of individual atoms in the resulted heterojunction, which make either
19
20 VBM or CBM; the partial density of state (PDOS) are calculated which are shown in (Fig.
21
22
23
24
25
26
27
28
29
30
31
32 18).
33
34
35
36
37

53 **Fig. 18** PDOS plots of $BiVO_4(001)$ and gC_3N_4 in $gC_3N_4@BiVO_4$ heterojunction.²⁷
54
55
56
57
58
59
60

1
2
3
4 In case of g-C₃N₄@BiVO₄ heterojunction, the VB is occupied by the N and C orbitals of
5
6
7 g-C₃N₄, while the CB is dominated by the 5d anti-bonding orbitals of V of BiVO₄. With
8
9
10 respect to the vacuum level, both the VBM and CBM of g-C₃N₄@BiVO₄ heterojunction
11
12
13 are situated at -6.16 and -3.70 eV, respectively, which has nice correlation with our
14
15
16 experimental data. As can be seen from (Fig. 18), the VB and CB of heterojunction are at
17
18
19 appropriate position while the Fermi energy result an internal electric field in the
20
21
22 heterojunction; responsible for efficient photogenerated electrons and holes. The
23
24
25 photogenerated electrons from CB of g-C₃N₄ directly reduce water and produce H₂ while
26
27
28 holes at VB of BiVO₄ directly oxidize water and results O₂. On the other hand, electrons
29
30
31 from CB of BiVO₄ recombine with the holes from the VB of g-C₃N₄. Finally, the internal
32
33
34 built in van der Waal interactive forces (at the interface of g-C₃N₄@BiVO₄) will reduce the
35
36
37 charge recombination.
38
39
40
41
42
43
44
45

46 The charge transfer between g-C₃N₄ and BiVO₄ in g-C₃N₄/BiVO₄ heterojunction was
47
48
49 calculated from the charge density difference of the g-C₃N₄/BiVO₄ heterostructure, and
50
51
52 the results are shown in (Fig. 19). The blue shaded areas represent charge accumulation
53
54
55
56
57
58
59
60

1
2
3 and depletion, respectively, so charge distribution occurred at the interface of g-
4
5
6
7 $C_3N_4@BiVO_4$ heterostructure. The charge redistribution at $g-C_3N_4@BiVO_4$
8
9
10 heterostructure led us to predict that the electrons from the CB of $g-C_3N_4$ reduce water
11
12
13 while the holes at the VB of $BiVO_4$ oxidize water to produce O_2 . The quantity of this
14
15
16 change of charge density is calculated from Bader charge analysis of the $g-C_3N_4/BiVO_4$
17
18
19
20
21 heterostructure which is about 0.056 electrons.
22
23
24
25

49 **Fig. 19.** Electrostatic potential map of $g-C_3N_4@BiVO_4$ heterojunction along Z-direction.²⁷
50
51
52

53 4. Conclusion 54 55 56 57 58 59 60

1
2
3
4 The effect of gamma radiation on the photoelectrochemical performance of and its
5
6
7 heterojunction ($g\text{-C}_3\text{N}_4@BiVO_4$) have been carried out, characterized and confirmed by
8
9
10 X-Ray diffraction (XRD), Fourier-transform infrared (FT-IR), X-ray photoelectron
11
12
13 spectroscopy (XPS), Field Emission Scanning Electron Microscopy with Energy
14
15
16 Dispersive X-Ray (FESEM-EDX), Ultraviolet and visible (UV-Vis), Atomic force
17
18
19 microscope (AFM), Profilometer, Photocurrent Density (LSV), and Density Functional
20
21
22 Theory (DFT) simulations. It is observed that the gamma radiation changes the structural
23
24
25 and chemical structure of the semiconductor which ultimately improve the overall PEC
26
27
28 efficiency. The band gap energy of gamma irradiated $g\text{-C}_3\text{N}_4$ reduces from 2.82 to 2.76
29
30
31 eV and the photocurrent density became two times to that of non-irradiated one;
32
33
34 increased from 3.59 to 5.86 $\mu\text{A cm}^{-2}$ at 1.23V vs. Ag/AgCl. Furthermore, the irradiated $g\text{-}$
35
36
37
38 C_3N_4 was combined with $BiVO_4$ to form $g\text{-C}_3\text{N}_4@BiVO_4$ heterojunction, which has also
39
40
41
42 two-timed photocurrent compared to that of non-radiated heterojunction; increased from
43
44
45
46 0.53 to 1.38 mA cm^{-2} . In summary, two different strategies have been applied (gamma
47
48
49 radiation and heterojunction) on a single photoelectrode which has effectively increase
50
51
52
53 the photoelectrochemical (PEC) efficiency of solar water splitting.
