24

25

26 **Abstract**

27 **Background:** The UK has one of the highest prevalence rates of obesity worldwide.
28 Public health departments have a duty to provide some obesity treatment and
29 prevention services. With evidence of effective programmes lacking, we investigate
30 lessons learned from a healthy weight programme in Cornwall, UK.

31 **Methods:** Data from the 12-week multi-component adult healthy weight
32 management programme were obtained for 2012-2016. Descriptive statistics and
33 statistical tests were used to describe participants' demographics; health status; and
34 anthropometric measures to explore the enrolment and retention of the programme
35 as well as the impact.

36 **Results:** A total of 1,872 adults were referred into the programme. 646 completed
37 the programme and, 48.8% achieved the programme's aim of a >3% reduction in
38 weight. Those who completed and met the programme aim tended to have had
39 healthier outcomes at baseline.

40 **Conclusions:** For those who engage with the programme the impact can be
41 meaningful. However, less than 1% of the population of Cornwall with overweight or
42 obesity enrolled in the programme, and those who benefitted most might have been
43 in least need. Providing services that meet the needs of the population is challenging
44 when a variety of services is needed, and the evidence base is poor.

51

52

53 **Introduction**

54 The rise in obesity and associated non-communicable diseases (e.g. co-morbidities
55 including type II diabetes, some cancers and cardiovascular diseases) represents a
56 major global public health challenge (1, 2). The UK has one of the highest
57 prevalence rates of obesity worldwide, which reached 27% of the adult population in
58 2015 (3). Wang, McPherson (4) predicted that this would rise to over 40% by 2030
59 with an additional 11 million more obese adults (3.3 million of whom could be older
60 than 60 years). They estimated that this increase in prevalence would cost the NHS
61 an additional £1.9-2 billion/year to treat the associated burden of disease (5).

62 The causes of obesity are many and extremely complex, involving a diverse range of
63 direct (e.g. biology, food consumption, activity levels and psychology) and indirect
64 (e.g. food production, wider environment and societal influences) factors, with levels
65 of physical activity and diet playing an important role (1, 6). Despite the potential of
66 prevention programmes, there appears to be limited robust evidence on successful
67 population-level intervention strategies to reduce obesity levels (7-12).

68 This is crucial as identifying effective strategies has the potential to prevent larger
69 disease burden on society and healthcare systems (2). Even a 1% BMI reduction
70 (approximately 1 kg weight reduction per person) across the UK could avoid
71 179,000–202,000 incident cases of diabetes, 122,000 cardiovascular diseases, and
72 32,000–33,000 incident cases of cancer (5). Consequently, obesity prevention is a
73 UK public health priority (13).

74 Following the UKs Health and Social Care Act 2012, Public Health services were
75 integrated into local authorities to improve the health of the local population. Public
76 Health departments have the remit to provide healthy weight programmes, including
77 both obesity prevention and treatment services. However, healthy weight
78 programmes vary across the country, with local authorities choosing to focus
79 primarily on promoting healthy eating (e.g. reducing energy intake) and/or increasing
80 physical activity (e.g. increasing energy expenditure) (13). The evidence on the
81 potential of these different approaches to increase quality of life, reduce morbidity
82 and premature all-cause mortality in adults with obesity varies and does not
83 necessarily support local decision making about the most appropriate approach to
84 adopt (10, 14, 15).

85 Four years of administrative / operative data from the evidence based Healthy
86 Weight Adults Programme adopted by Cornwall Council, South West of England
87 have been examined in order to assess the impact of the programme and identify
88 opportunities for programme development.

89 **Methods**

90 **Context**

91 Cornwall is a predominantly rural county, with many small dispersed settlements.
92 Some of the most deprived communities in England (16) are in Cornwall and are
93 associated with lower life expectancies (17). Addressing physical inactivity and
94 unhealthy diets in adult populations are current public health priorities because
95 64.3% of adults in 2016/17 fall within the overweight and obese category across
96 Cornwall (18). Details of the care pathway for adults with overweight or obesity in the
97 county can be found in online repository #1.

98 **Healthy weight adult programme**

99 The programme is a lifestyle management programme for adults aged 18+ years
100 who are above a healthy weight ($BMI > 25 \text{ kg/m}^2$). The aims of the programme were
101 to achieve a 3 to 5% weight loss through 6- and 12-month follow up appointments as
102 well as increasing physical activity and improving diet. It is a 12-week multi-
103 component lifestyle weight management programme, employing motivational
104 interviewing and health coaching techniques to promote healthy eating and physical
105 activity. Each weekly session consists of a two-hour intervention focusing on
106 education and physical activity (an hour on each). The physical activity and exercise
107 advice are based on Chief Medical Officer's recommendations (e.g. type, frequency
108 and intensity of activity for health) for Physical Activity for Adults (20). Dietary advice
109 is based around the Eatwell Guide (21). Sessions are held in a community setting
110 and delivered by two trained Healthy Lifestyle delivery advisors. Participants are
111 offered the opportunity to attend 3-, 6-, 12- and 24-month reunions for the
112 assessment of longer term changes in behaviour and weight.

113 Written consent from participating adults is obtained from each of the registration
114 days, which requires a commitment to completing the 12-week programme, as well
115 as, being motivated and ready to change. Adults are not registered onto the

116 programme if they have; an underlying medical cause for obesity and would benefit
117 from more intensive clinical management than a tier 2 service; significant co-
118 morbidity or complex needs as identified by their GP or healthcare professional; an
119 eating disorder; or a BMI <25 kg/m².

120 **Data**

121 This study was an analysis of the operational data from the Healthy Weight Adults
122 programme. The following anthropometric measures were taken at registration
123 (week 1), programme completion (week 12) and then at each reunion; height (Seca
124 213 Portable Height Measure), waist circumference (Seca measurement tape),
125 weight, fat mass, muscle mass, visceral fat and metabolic age (Tanita Body
126 Composition Analyser). On entry to the programme, the advisor completes a
127 registration form and check list with each participant. This includes asking
128 information about previous or ongoing weight management strategies, importance of
129 making long-term changes, realistic weight-loss goals and commitment to completing
130 the programme. The registration form captures participant demographic
131 characteristics including, age, gender, ethnicity, level of deprivation (22) and
132 presence of any disability. Participant peak flow, systolic and diastolic blood pressure
133 were also taken (using CareFusion PulmoLife COPD Screening Device and the
134 Omron 705IT, respectively) during registration and on completion of the programme.
135 Participant physical activity was assessed during the programme using the validated
136 New Zealand Physical Activity Questionnaires and dietary behaviour using the
137 validated Short Form Food Frequency Questionnaire, but these measures are not
138 included in the current study.

139

140 **Statistical analyses**

141 Body Mass Index (BMI) was calculated as follows for each participant; weight (kg)
142 divided by height² (m²), and categorised as shown in online repository #2. Waist-
143 Height ratio (WHtR) was also calculated as waist circumference (cm) divided by
144 height (cm) as another measure of obesity which particularly reflects abdominal
145 obesity. The nature of the association between WHtR and morbidity and mortality is

146 not confirmed, but as a rule of thumb a WHtR over 0.5 is considered to indicate
147 increased risk (23-25).

148 Descriptive statistics were used to examine participant flow through the programme
149 and data completeness. In order to compare participants in the programme with non-
150 participants, baseline data for those who completed the programme were compared
151 with those who dropped out after registration.

152 The difference between each participant's baseline and follow-up measures was
153 calculated for each outcome at each time point (completion, 3-, 6-, 12- and 24-
154 month). These differences were then averaged to give a mean difference and 95%
155 confidence interval. Changes in weight status were also categorised according to
156 BMI and WHtR.

157 Finally, as sustained weight loss was the goal of the programme, a comparison was
158 made in the baseline demographics and anthropometrics between those who had
159 and had not demonstrated >3% reduction in weight at 12 months.

160 Ethical approval for this study was granted by Cornwall Councils Research
161 Governance Framework panel on the 16th August 2017, and the University of Exeter
162 Medical Schools ethics committee on the 28th September 2017 (reference number
163 17/08/133).

164

165 **Results**

166 Eligible adults could self-refer into the healthy weight programme or be referred from
167 primary care or other health professionals. Of those being referred into the
168 programme during 2016, 82% had self-referred and only 9% had been referred by
169 GP's or practice nurses (19). Between 2012 and 2016, a total of 1,872 adults were
170 referred into the programme.

171 Of the 1,872 adults being referred onto the programme, 74 (4.0%) cancelled before
172 registering and 101 (5.4%) failed to attend the registration appointment (Figure 1). A
173 total of 1,697 people were reported to have registered on the programme, but
174 anthropometric measures were only recorded for at most 952 (56.1%) people. Only
175 646 (38.1%) people completed the 12-week programme with anthropometry

176 available for at most 644 adults (99.7%). There appears to have been an early drop
177 out around week 2 and then a later one around half way through the programme.
178 Some participants were measured at follow-up without being measured at
179 registration (baseline) and therefore, have not been included in any further analysis.
180 The number of participants attending each reunion fell, with only 80 participants
181 attending their 24-month reunion (Figure 1).

182 Participants completing the programme had a mean age of 57.4 years with a mean
183 weight of 99.2 kg and 92.3% were from a White British background (Table 1). Nearly
184 a quarter (23%) of participants had a disability and 77.3% of participants completing
185 the programme were women. Levels of obesity and waist-height ratio varied, and
186 despite the inclusion criteria a small number of people with $BMI < 25\text{kg}/\text{m}^2$ appear to
187 have participated in the programme.

188 There were no statistically significant differences between completers and non-
189 completers in terms of gender, ethnicity, Waist-Height ratio category, visceral fat,
190 blood pressure or peak flow. Blood pressure and peak flow measures were available
191 for less than 20% of the sample and therefore may be more biased than the other
192 measures. There was a borderline significant difference in the proportion reporting a
193 physical or learning disability, where a higher proportion dropped out. People who
194 completed the programme tended to be older ($p < 0.01$) and were more likely to be
195 from deprivation quintiles 1-3 (highest deprivation) than 4 or 5 ($p = 0.03$). In terms of
196 the anthropometric measures those who dropped out had less healthy measures.
197 Metabolic age was around 2 years higher among the completers ($p < 0.01$), but they
198 were around 5 years chronologically older ($p < 0.01$), demonstrating that completers
199 tended to be healthier. Understandably as a referral programme, participants in the
200 programme had a poorer weight profile than the general public, however, people
201 who remained in the programme tended to be healthier than those who dropped out.

202 Of the 642 participants with data on weight at programme completion, 48.8% had
203 achieved the aim of greater than 3% reduction in weight compared to when they
204 registered (24.6% had achieved greater than 5%). Twelve-month reunion data were
205 only available for 185 participants, of whom 49.2% (>5% 38.4%) were demonstrating
206 greater than 3% weight loss compared with registration. A quarter (>5% 45.1%) of
207 these participants achieved this loss after programme completion. However, these

208 figures mean that only 14.2% of those completing are known to have achieved the
209 goal 12-months following programme completion with data unavailable for 71.4% of
210 participants. None of the mean differences in any of the outcomes were found to be
211 statistically significant at any of the time points (Table 2). Overall, apart from peak
212 flow and muscle mass which would increase if they were improving, the mean
213 difference for each measure indicated improvement. There were demographic and
214 anthropogenic measure differences in adults who had and had not achieved a
215 meaningful (<3%) reduction in weight at 12-months (Table 3).

216 In our analyses of changes in weight status (Online repositories #3-7), the results
217 tended to be poorer in terms of WHtR but, there were anomalous changes (shown
218 highlighted in blue) which may indicate an issue with data collection. The majority of
219 people remained the same weight status between time points, but a minority of
220 people did move into a healthier weight status. In terms of BMI, around one third of
221 people who were obese category 1 or 2 moved to a lower weight status.

222 **Discussion**

223 **Main findings of this study**

224 Over a four-year period, out of an adult population of around 434,000 (mid-2017
225 estimates (26)) almost 1,900 adults in Cornwall were referred to the Tier 2 healthy
226 weights adults programme with the majority being self-referrals, however, only a third
227 completed the programme. Those who completed the programme were older, from
228 more deprived areas, and had healthier anthropometric measures at baseline.
229 Almost 50% of those who completed the programme achieved the aim of greater
230 than 3% weight reduction, with 75% of those maintaining the weight loss for 12
231 months. However, these changes did not result in statistically significant impacts on
232 any of the other outcome measures assessed, with significant loss to follow up
233 reducing the sample size (Table 2). The small number of potential harms from the
234 programme may include reductions in peak flow and muscle mass. However, without
235 information on age related decline in these measures it is not possible to assess
236 whether these are consistent with age related decline. Those who had achieved
237 greater than 3% weight loss by the 12-month reunion were more likely to be female
238 and had lower levels of visceral fat at baseline (registration).

239 As the data analysed did not originate from a trial the objective of this study was to
240 investigate how the programme and other programmes serving similar populations
241 could be improved. There are a wide number of reasons that someone may not have
242 attended a reunion which may have biased the findings to a greater and lesser
243 extent (e.g. prior commitments or avoidance due to fear of having regained weight).
244 The comparison between the baseline characteristics of those who did and did not
245 complete the programme suggest that those who dropped out were less healthy.
246 Those who had achieved or maintained a >3% weight reduction by 12-months also
247 appear to have been healthier than those who did not meet that programme aim.
248 This may suggest that the programme struggled to have an impact upon those at
249 greatest need for intervention.

250 **What is already known on this topic**

251 According to Public Health Profiles 64.3% (95% confidence interval 60.5% to 68.1%)
252 of the adult population are overweight or obese (18). However, over a four-year
253 period 0.4% of that adult population were referred into the Cornwall Healthy Weight
254 Adults programme. The majority of these were self-referrals, which suggest that
255 people are seeking interventions to improve their weight status, and also that health
256 care professionals were not referring patients to the programme. This may reflect a
257 lack of awareness of the programme, a lack of confidence amongst healthcare
258 professions around discussing weight status, or that those with overweight or obesity
259 are not ready to change.

260 While the National Institute for Health and Care Excellence 2014 guidance on
261 obesity identification, assessment and management include a number of
262 recommendations regarding behavioural and lifestyle interventions, the evidence on
263 effective interventions remains lacking (27-33). Therefore, while local authorities
264 have a duty to provide services, the selection of an effective intervention is difficult,
265 especially when budgets continue to be cut, and these services are competing with
266 more evidence-based services. This issue is compounded in counties like Cornwall
267 where there is a need to provide public health programmes across a large rural area
268 with limited transport links and pockets of high deprivation. These issues may have
269 resulted in the low and potentially inappropriate uptake of the programme. A small
270 number of people with healthy weight and larger numbers of people with (category 2

271 or 3) obesity undertook the programme, (Table 1), for this latter group Tier 3 or 4
272 services may have been more beneficial but these services require the patient to
273 meet more specific referral criteria (34). The reviews of behavioural interventions to
274 date have excluded people with morbid obesity ($BMI \geq 40 \text{ kg/m}^2$) (27, 32, 33), whereas
275 Tier 3 interventions have been found to achieve at least a 5% reduction in initial body
276 weight in those completing the programme (35).

277 **What this study adds**

278 We conducted this study to refine the ongoing delivery of the tier 2 healthy weights
279 adult's programme. While participants primarily self-referred into the programme,
280 these represented less than 1% of the adult population of Cornwall with overweight
281 or obesity. Drop out and incomplete data were significant issues, particularly as the
282 data available suggest that those who remained with the programme tended to be
283 healthier at baseline. Around half of those who completed the programme met the
284 aim of achieving greater than 3% weight reduction, indicating that there may be
285 some benefit of the programme for specific individuals. However, the factors that
286 contribute to the development of overweight and obesity vary between individuals
287 and therefore the most effective treatment varies. This is an important challenge to
288 future service design, delivery and commissioning, which is exacerbated when the
289 service needs to be delivered across a sparse rural area. Although, the level of
290 deprivation and rural isolation in Cornwall is unusual, most counties in the UK have
291 rural and aging populations in need of obesity prevention services and therefore face
292 the challenge of identifying and providing suitable interventions. However,
293 interventions to impact on those socioeconomic conditions which contribute to many
294 poor health outcomes (including obesity) would be preferable to high-effort
295 approaches like this tier 2 programme (36). In the absence of such interventions
296 based on this research tier 2 healthy weight programmes in sparse rural areas would
297 benefit from including online options and integrating into workplaces. Tailoring the
298 scale and intensity of programmes according to different levels of need may also
299 help improve retention rates and intervention outcomes.

300 **Limitations of this study**

301 A number of limitations exist in this study. Firstly, the study was limited due to the
302 number of drop outs across the programme, as well as, quality control issues such

303 as missing or invalid data. For example, following this study it was discovered that
304 the method used to collect waist circumference data was not reliable and no longer
305 recommended by the National Institute for Health and Care Excellence (NICE).
306 Consequently, this measure is no longer used which might explain the unusual
307 results in terms of Waist-Height ratio categories. The greatest challenge to
308 interpreting these data is that they do not originate from an experimental study, and
309 therefore we cannot attribute the results to the programme. A preferably randomised
310 controlled study would be required; however, such an experiment could be
311 logistically challenging due to limited venues and resources. Moreover, an
312 experiment is ethically challenging, as we would need to be uncertain about whether
313 a programme is beneficial. Can we deny someone the opportunity to lose weight,
314 even if it is uncertain if the specific programme will lead to meaningful weight loss for
315 them? With funding for programmes and research limited we need to learn whatever
316 lessons we can from the interventions being implemented by local public health
317 departments, potentially identifying new programmes to be rigorously evaluated.

318 **Acknowledgements**

319 We would like to thank the University of Exeter Medical School and the Health and
320 Wellbeing Service from Cornwall Council for their role in developing and
321 implementing the evaluation of the Healthy Weight programme.

Peak flow		88.1±24.2	16	80.6±21.0	12	0.40

*mean±standard deviation for continuous outcomes and percentages for categorical outcomes

†p-values comparing those who had and had not achieved a meaningful reduction in BMI using t-tests for continuous outcomes and chi-squared tests for categorical outcomes

Online repository**#1 – Cornwall and Isles of Scilly Care Pathway for overweight and obese adults**
September 2018

#2 – Weight status cut-points for body mass index and waist-height ratio

	Body Mass Index (BMI)*	Waist-Height ratio (WHtR)	
		Male	Female
Underweight	<18.5	<0.43	<0.42
Healthy weight	≥18.5 and <25	≥0.43 and <0.52	≥0.42 and <0.48
Overweight	≥25 and <30	≥0.52 and <0.57	≥0.48 and <0.53
Obese category 1 (cat 1)	≥30 and <35	≥0.57 and <0.62	≥0.53 and <0.57
Obese category 2 (cat 2)	≥35 and <40	-	-
Obese category 3 (cat 3, morbid)	≥40	≥0.62	≥0.58

*These BMI cut points apply to adults (≥18 years old); the youngest people in the dataset are 17 but these cut points have still been used.

#3 – Changes in weight status from registration (baseline) to completion in terms of (a) body mass index (BMI) and (b) Waist-Height ratio (WHtR)

a	BMI	COMPLETION (12 weeks)					TOTAL
		Healthy weight	Overweight	Obese – category 1	Obese – category 2	Obese – category 3	
BASELINE	Healthy weight	100.0%	0.0%	0.0%	0.0%	0.0%	0.9%
	Overweight	4.3%	91.5%	4.3%	0.0%	0.0%	10.1%
